use this information to help you with your further assessment. Use the AVPU scale (Awake and alert, responsive to Verbal stimuli, responsive to Pain, Unresponsive) to determine the patient's level of consciousness.

Anatomic changes that occur as a person ages predispose geriatric patients to airway problems. Aging and disease can compromise a patient's ability to protect the airway with loss of a gag reflex and normal swallowing mechanisms. Changes in level of consciousness, dementia, and weakness or paralysis resulting from stroke can cause airway obstruction or aspiration. Ensure that the patient's airway is open and is not obstructed by dentures, vomitus, fluids, or blood. Suction may be necessary.

Anatomic changes with aging also affect a person's ability to breathe effectively. Increased chest wall stiffness, brittle bones, weakening of the airway musculature, and decreased muscle mass contribute to breathing problems. Loss of mechanisms that protect the upper airway, like cough and gag reflexes, cause a decreased ability to clear secretions. A decrease in the number of cilia that line the bronchial tree results in the inability of the patient to remove material from the lungs, which can cause infection. In some patients, the alveoli are damaged, and a lack of elasticity results in a decreased ability to exchange oxygen and carbon dioxide. Superimposed on the physiologic changes are the chronic respiratory diseases common in older people that affect the ability of the patient to breathe effectively. Airway and breathing issues should be treated with oxygen as soon as possible.

Poor perfusion is a serious issue in an older adult. People who normally live with compromised circulation have little in the way of reserves during a circulatory crisis. Physiologic changes may negatively affect circulation. Less responsive nerve stimulation may lower the rate and strength of the heart's contractions, so lower heart rates and weaker and irregular pulses are common in geriatric patients. Vascular changes and circulatory compromise might make it difficult to feel a radial pulse on an older patient. If choosing an alternative pulse point like the carotid, press gently. Another option is to listen to the apical pulse right over the heart. The pulse may be irregular because of common heart rhythm problems. Apply supplemental oxygen as needed for an SpO₂ below 94%.

Patient assessment is more complicated in an older adult, and multiple problems can exist. Any problems that compromise airway, breathing, or circulation should result in transportation of the patient on a priority basis. Priority patients include those who have any of the following:

- A poor general impression
- Airway or breathing problems
- Acute altered level of consciousness
- Shock
- Any severe pain
- Uncontrolled bleeding

Older people do not have the reserves that younger people do, and they will easily decompensate. Even a general report of weakness and dizziness can be an indication of something more serious, like a heart problem. Consider paramedic rendezvous and provide immediate treatment and transport to the closest, most appropriate facility.

Many acronyms are used in the prehospital setting to help you remember steps in your assessment and treatment. The GEMS diamond (the components of which are Geriatric patients and Environmental, Medical, and Social assessments) was created to help providers recall key themes when caring for geriatric patients (**TABLE 37-1**).

The “G” of the GEMS diamond calls on you to recognize that the patient is a geriatric patient. In such a case, your thought process needs to be geared to the possible problems of an aging patient.

The “E” of the GEMS diamond stands for an environmental assessment. Preventive care is important for an older patient, who may not carefully study the environment or may not realize where risks exist. For example, if you walk into a room and trip over a rug, you should mention it to bring potential hazards to the patient’s attention. Assessment of the environment can help give clues regarding the patient’s condition. Are there hazardous conditions? Preventive interventions for geriatric patients include reviewing the home environment to ensure that safe and livable conditions exist, providing information on preventing falls, and making referrals to appropriate social services agencies when needed.

The “M” of the GEMS diamond stands for medical assessment. Older patients tend to have a variety of medical problems and may be taking numerous prescription, OTC, and herbal medications.

Obtaining a thorough medical history is important in older patients.

The “S” stands for social assessment. Numerous social agencies are readily available to help the older patient. Many agencies can provide assistance to our older population, but they must be made aware of the need. Older people may be too proud to ask for help, may not want others to know they need assistance, or may be wary of a financial cost. Consider obtaining information pamphlets about some of the agencies for older people in your area. If you have these brochures with you and encounter a person in need, you can provide this valuable information. Social agencies that work with the older population will be able to provide a listing of their services.

History Taking

It is often said that 80% of a medical diagnosis is based on the patient’s history. In addition to clearing the airway and managing the ABCs (airway, breathing, and circulation), obtaining a thorough history is one of the most important things you can do. An inaccurate or inadequate history can lead to an incorrect field impression, which may result in an inappropriate treatment plan.

To obtain an accurate history, patience and good communication skills are essential. An older patient’s diminished sight, hearing, and speaking ability may hamper communications. If possible, take a few moments to have the patient insert dentures or a hearing aid or, if necessary, assist the patient in doing any of these things. All of these items can help the patient to communicate with you more effectively.

Words of Wisdom

Remember that patients’ medications are a vital part of their history. Don’t forget to include any OTC medications or herbal remedies in the history.

An older patient can have multiple problems, or the primary issue can be caused by a secondary problem. Many patients will only reveal a lesser problem during questions asked in your assessment. Additionally, they may not consider the

TABLE 37-1 The GEMS Diamond**G Geriatric Patients**

- Present atypically.
- Deserve respect.
- Experience normal changes with age.

E Environmental Assessment

- Check the physical condition of the patient's home: Is the exterior of the home in need of repair? Is the home secure?
- Check for hazardous conditions that may be present (eg, poor wiring, rotted floors, unventilated gas heaters, clutter that prevents adequate egress).
- Are smoke detectors present and working?
- Is the home too hot or too cold?
- Is there an odor of feces or urine in the home?
- Is bedding soiled or urine soaked?
- Are pets well cared for?
- Is food present in the home? Is it adequate and unspoiled?
- Are liquor bottles present? If so, are they empty?
- Are there burn patterns on the walls, cabinets, or floors?
- Are there unsecured throw rugs that could result in falls?
- If the patient has a disability, are appropriate assistive devices (eg, a wheelchair or walker) present and in adequate condition?
- Does the patient have access to a telephone?
- Are medications prescribed to someone else, expired, unmarked, or from many physicians?
- If living with others, is the patient confined to one part of the home?
- If the patient is residing in a nursing facility, does the care appear to be adequate to meet the patient's needs?

M Medical Assessment

- Older patients tend to have a variety of medical problems, making their assessment complex. Keep this consideration in mind in all cases, both trauma and medical. A trauma patient may have an underlying medical condition that could have caused or may be exacerbated by the injury.
- Obtaining a medical history is important in older patients, regardless of the chief complaint.
- Perform a primary survey.
- Perform a reassessment.

S Social Assessment

- Assess activities of daily living (eating, dressing, bathing, toileting).
- Are these activities being provided for the patient? If so, by whom?
- Are there delays in obtaining food, medication, or toileting? The patient may complain of such a delay, or the environment may suggest a problem.
- Does the patient have regular visits from family members, live with family members, or live with a spouse?
- If in an institutional setting, is the patient able to feed themselves? If not, is food still sitting on the food tray? Has the patient been lying in their own urine or feces for prolonged periods?
- Does the patient have a social network? Does the patient have a mechanism to interact socially with others on a daily basis?

© Jones & Bartlett Learning.

secondary problem to be important. You will have to play the role of detective many times to determine the actual problem. The more facts and information that you can obtain from the patient and bystanders or caregivers, the more informed your treatment decision will be.

The patient who is in respiratory distress may not report shortness of breath, but may report feeling dizzy. Are the two problems related? A patient who is hypoxic will report being dizzy. Often a syncope episode is the only indication of a cardiac dysrhythmia. Older patients can develop a tolerance to

their diseases. Many have been able to modify their lifestyles to their diseases. In addition, some older patients do not want to bother anyone. This mind-set causes a delay in seeking help and may exacerbate the patient's condition.

When a patient's chief complaint seems trivial, it may be necessary to go through a standard list of screening questions to confirm that you are not missing important pieces of information. In such a review of systems, the questions are designed to evaluate the functions of the body's major organ systems. In the field, you do not have sufficient time to conduct a complete review of all systems, but a few well-chosen questions can provide you with a great deal of information about the function of the patient's more important systems:

- Cardiovascular
 - Have you had any pain or discomfort in your chest? When?
 - Have you had any pain in your left arm or jaw?
 - Have you noticed any fluttering in your chest or fast heartbeats?
- Respiratory
 - Are you ever short of breath? When?
 - Have you had a cough lately? Is it painful and, if productive, what color?
 - What position have you been sleeping in? (Recall that patients with heart failure may find themselves sleeping in an upright position in bed, with pillows behind their back, or in a reclining chair.)
- Neurologic
 - Can you explain the reason for calling 9-1-1?
 - Have you had any dizzy spells? Have you fainted?
 - Have you had any trouble speaking?
 - Have you had headaches recently?
 - Have you noticed any unusual weakness or odd sensations in your arms or legs?
- Gastrointestinal
 - Have there been any changes in your appetite lately?
 - Have you gained or lost any weight?
 - Have there been any changes in your bowel movements?
 - Have you had any nausea or vomiting?
- Genitourinary
 - Do you have any pain or difficulty urinating?

- Have you noticed any change in the color of your urine?
- Have you noticed any changes in the frequency of urination?

If any of these screening questions yields a positive answer, follow up with further questions. For example, if the patient states that they have been coughing lately, find out whether they are bringing up sputum and, if so, what the sputum looks like (eg, is there blood in the sputum?).

Getting an accurate SAMPLE history (Signs and symptoms, Allergies, Medications, Pertinent past medical history, Last oral intake, Events leading up to the illness or injury) can be complicated, especially in a patient who has an altered mental status. You may have to depend on a relative or caregiver to help you in collecting a SAMPLE history, including allergies to food and medications.

The last meal is particularly important in a patient with diabetes, but lack of nutrition can have a negative effect on any patient. A history of last oral intake can indicate that the patient may be dehydrated. Finally, what is the event that prompted the call? In addition, it is advantageous to provide transport to a facility that “knows” the patient's medical history if the patient's condition and other factors allow, as long as that facility has the capability to handle the patient's current problem.

Most important, you should obtain the most detailed history possible of the patient's medications, because medications account for a substantial percentage of medical problems in older people. A medication history should include all medications, not just prescription drugs, because many people do not think to mention common OTC preparations such as aspirin, antacid tablets, and herbal medicines. Ask the patient to list the medications by name, and determine the dosing and frequency for each one. Also, inquire about medications that are prescribed but not taken (eg, because of cost issues or side effects) and medications that may have been provided by other sources (eg, a spouse's medication). Obtain the patient's permission to take medications to the hospital, and then collect them all (prescription and nonprescription) and include the information in your documentation. If the patient cannot tell you where the medicines are stored, check the bathroom medicine cabinet, the bedside table, the kitchen table and counters, and the refrigerator.

FIGURE 37-7 Medication containers such as the Vial of Life can be provided to older patients to keep track of medical information.

© American Academy of Orthopaedic Surgeons.

Many older patients will have a written list of their medication names and dosages. Some agencies have provided medication lists for older patients to use. Some of these are known as the Envelope of Life or Vial of Life and are placed on or in the refrigerator (**FIGURE 37-7**). A sticker or magnet that is affixed to the refrigerator or front door will often alert EMS providers that there is important patient information available, such as the patient's medical history, current medications, and allergies.

Some patients may not recall the actual name of their medications and may refer to them by color or what they are prescribed for: "I take the little blue one for my heart at night and the pink one for my blood pressure twice a day." This information may also help determine pertinent past history. The opposite end of the spectrum is possible when a patient hands you a shopping bag full of medications. Many of the bottles may be empty or outdated, and there may be numerous medications from different physicians or hospitals. Assess compliance by checking the fill dates on the bottles. This action also may help you to determine if the patient has been taking medications regularly.

There are many commercially available medication reminders and containers. The most common

is the weekly pill box. This box is divided into days of the week. The patient (or another responsible party) fills the box with the medication for the week, separated into the 7 days. Many older patients rely on this pill box to recall if they have taken their medication for the day. You can be aware of the patient's medication compliance by checking the box. Many patients will leave open those days in which they have taken their medication. It is important to find out who fills the box and on what day it is normally filled. There are also electronic versions of the same device that will emit a beeping sound when it is time to take the medication.

Obtaining a history from an older patient requires patience. You must be prepared to listen, often for an extended period. However, your listening will be rewarded—not only by helping you discover the patient's problem, but also by allowing you to provide part of the solution to the problem. Listening is a demonstration of caring, and your caring can mean a great deal to a lonely or frightened older person.

Dizziness or Weakness

Obtaining an accurate history of a patient complaining of dizziness or weakness is often difficult with an older patient. This problem can be caused by a cardiac problem, infections with the inner ear, hypotension, or hypertension. During your assessment, it is important to check the patient's pulse and motor and sensory function in all extremities as the patient may be experiencing a stroke. Ask the patient if the weakness, dizziness, or both are always present or if they only occur during certain activity.

Fever

You may be called for a patient who has a fever. This is the body's immune response to combat an infection. Consider the circumstances surrounding the fever. Is the patient unresponsive or does the patient have an altered mental status? Is the patient septic? When was the fever first noticed?

Pain

The OPQRST-I mnemonic (Onset, Provocation/palliation, Quality, Region/radiation, Severity, Timing, and Interventions) will help you understand more about the patient's pain. Remember that as the

body ages, pain sensation changes. Many older patients live with daily pain; ADLs are often modified because of the pain. Consider the current weather when assessing a patient's pain; many patients experience an exacerbation of pain when the weather changes. Is the pain of an acute onset, or has it been developing over a period of days or weeks? Were OTC medications used? If so, did they help to alleviate the pain?

Words of Wisdom

If a patient tells you that their pain is chronic, determine if its onset was slow and progressive or acute. The patient may have experienced an acute onset of pain 1 week ago; however, because the pain worsened, EMS was called. Many patients will interpret an acute onset of gradually worsening pain as being "chronic."

Secondary Assessment

Be aware that the sensation of pain may be diminished in older patients, leading you to underestimate the severity of their condition. This diminished sensation is associated with the aging nervous system. The incidence of silent MIs (heart attacks) without the typical symptom of chest pain is greater in older patients, and these are often associated with a dire prognosis.²²

During the physical exam, protect the patient's modesty at all times. Inspection and palpation can be hampered by multiple layers of clothing; remove only the clothing that is necessary for an accurate assessment, and cover the patient when you are finished. Older people are more susceptible to hypothermia than are younger people. Be sure to keep the patient warm and maintain body temperature.

Street Smarts

Unless you have a true emergency situation, take care when removing an older patient's clothing for assessment. Use scissors wisely; this may be the only sweater, coat, or undergarment belonging to that person.

Vital signs may be different in older people because of the physiologic changes that come with aging, chronic disease, and the effects of medications. The heart rate should be in the normal adult range but may be compromised by medications such as beta-blockers. These medications keep the heart rate low and prevent the tachycardia that might be typically seen in dehydration or shock. Weaker and irregular pulses are common in older patients. The pulse may be irregular secondary to atrial fibrillation. Circulatory compromise may make it difficult to feel a radial pulse on an older patient, and other pulse points may need to be considered.

Blood pressure tends to be higher in older people. A geriatric patient who has a blood pressure in a normal adult range could be hypotensive. Hypertension could signal impending stroke. Try to confirm if the patient has missed taking any medications for hypertension.

Capillary refill is not a good assessment tool in older adults because of skin changes and reduced circulation to the skin.

The respiratory rate should be in the same range as in a younger adult, but remember that chest rise will be compromised by increased chest wall stiffness. Be sure to auscultate breath sounds to listen for crackles (formally called rales) associated with

Assessment Pearls

- *Never* assume that an altered mental status is normal for a geriatric patient. Establish a baseline mental status if possible, and quickly assess for hypoxia and hypoglycemia.
- Trauma may have a medical origin. Question the patient and bystanders about any dizziness, weakness, or other complaint prior to a fall.
- Gather *all* medications, including herbal remedies and vitamins, to take with you to the hospital.
- Take care when packaging a geriatric patient, adding additional padding for comfort where needed.
- Use IV fluid judiciously so as not to overload the circulatory system, induce pulmonary edema, or increase blood pressure in patients who may already be hypertensive.
- Unless the patient has a history of Parkinson disease, shaking or trembling movements may be a focal seizure.

pulmonary edema, rhonchi associated with pneumonia, and wheezes associated with asthma.

Careful interpretation of SpO_2 data is necessary in older adults because the pulse oximetry device requires adequate perfusion to get an accurate reading. Older adults may have poor circulation, vasoconstriction, hypotension, hypothermia, lack of red blood cells, or carbon monoxide poisoning that could result in an inaccurate reading. Adhesive probes, if available and used by local protocol, might help confirm accuracy of the data if poor peripheral perfusion is a concern.

Try to determine the patient's normal blood pressure. The baseline blood pressure obtained for this patient and any change from the patient's normal baseline can alert you to a potential problem.

Reassessment

Reassess the geriatric patient often because the condition of an older adult may deteriorate quickly. Repeat the primary survey. Reassess the vital signs. Reassess the patient's problem. Recheck interventions. Identify and treat changes in the patient's condition.

Communicate all findings and interventions provided to emergency department (ED) personnel. Document all history, medications, assessment, and intervention information and leave a copy of your documentation with the ED.

Emergency Medical Care

Typical interventions include positioning, oxygenation, administration of glucose, and psychological support. In specific cases, you may also assist with nitroglycerin, aspirin, or inhalers. An older patient reporting shortness of breath will want to sit up or assume the tripod position. Accommodations to these requests should be made except in cases in which you need to manage the patient's airway. The patient's position may be maintaining a patent airway. Forcing a patient supine who is short of breath may result in respiratory failure or arrest. Allow the patient to maintain a position of comfort, unless the patient is unable to maintain it, if possible. Assist ventilation as needed.

Administration of oxygen may be a useful therapy for many geriatric problems, including vague reports of weakness or dizziness, particularly if the

YOU are the Provider

Part 3

You immediately assist the patient back to the supine position once you note that he is demonstrating signs of orthostatic hypotension when standing. Your partner then leaves to get the stretcher and bring it to the bathroom door. Given this patient's confusion, you elect to check his blood glucose level. You discover that the patient's blood glucose level is normal. Suspecting substantial GI bleeding, you place the patient on 15 L/min of oxygen via a nonrebreathing mask, establish an 18-gauge IV line to his left antecubital fossa vein, and administer a 250-mL bolus of normal saline. While you are waiting for your partner to arrive with the stretcher, you obtain a complete set of vital signs, then review his medications, which his daughter has handed to you. You note bottles of warfarin (Coumadin), atenolol (Tenormin), metformin (Glucophage), and aspirin.

Recording Time: 6 Minutes

Respirations	26 breaths/min, normal
Pulse	Slow and thready, 52 beats/min
Skin	Cool, pale, and clammy
Blood pressure	72/36 mm Hg
Oxygen saturation (SpO_2)	96% on room air
Pupils	Pupils Equal, Round, and Reactive to Light and Accommodation (PERRLA)

- Does this patient require a second IV line?
- What is the significance of the medications that the patient is taking?

SpO₂ level indicates hypoxia. When administering oxygen, be mindful of monitoring the level of consciousness in a patient with COPD. Be prepared to ventilate if the patient's hypoxic drive becomes inadequate.

Other interventions include administration of glucose in a patient with diabetes who has altered mental status and a manageable airway. In a patient with a cardiac history, consider assisting with the patient's nitroglycerin if the person is having chest pain, or assist a patient with medication for asthma when the patient is experiencing shortness of breath.

Finally, and critically important in older adults, is providing emotional support. Older people are often fearful of what may be happening and that they may never return home from the hospital. Listen to your patient, respond to your patient, and provide reassurance.

Special Populations

Older adult patients are often anxious about leaving home, especially if they live alone. Helpful hints to put them at ease include leaving food and water for their pet, checking doors and windows and securing the residence, and reminding them to bring along a cell phone and charger.

Fluid Resuscitation in Geriatric Patients

Fluid resuscitation in an older person can be challenging. Because geriatric patients often have chronic hypertension, baseline values for blood pressure may be higher than those of other adults. Because of decreases in circulation along with atherosclerosis and arteriosclerosis, increased blood pressure may assist the body in achieving end organ perfusion. An older patient may actually be in shock with systolic pressures of greater than 100 mm Hg.

Modest amounts of blood loss can quickly result in shock in a geriatric patient because of the patient's inability to adapt and compensate quickly. Reduced blood volume, possible anemia, and medications such as beta-blockers also may interfere with coping mechanisms. Large volumes of fluid may result in circulatory overload and pulmonary edema. Monitor breath sounds frequently when

providing fluid resuscitation. Introducing fluid into the system of a geriatric patient can produce electrolyte alterations and hemodilution. Diluting the blood will decrease its ability to carry oxygen and result in hypoxia, as well as making clotting mechanisms less effective. Use fluid sparingly; you can always add more, but cannot easily take fluid out.

Words of Wisdom

Remember that the skin of the older patient tends to be very fragile. Try tying the tourniquet loosely or not using one at all when trying to gain IV access. Pull the skin taut to avoid "wrinkling" and be alert for the potential for excessive bleeding from attempts. For critical patients, do not hesitate to use the intraosseous route when gaining IV access is difficult.

Assessment and Management of Respiratory Emergencies

Shortness of Breath

Many of your older patient contacts will involve a patient reporting respiratory distress, either acutely or chronically. Remember that, in addition to the shortness of breath, another condition may be an underlying cause. Obtaining an accurate pertinent medical and prescribed medication history may help you determine the etiology of the problem (ie, respiratory versus cardiac). If the patient has a history of pedal edema, discomfort of the chest, and hypertension, the cause may be cardiac related. A productive cough and signs of emphysema point toward a respiratory condition.

Patients in respiratory distress should not be overwhelmed with questions. A bystander or family member may be able to answer your questions. It is important to find out whether the patient has a history of respiratory problems and what, if any, medications the patient is taking.

Patients experiencing respiratory distress should receive supplemental oxygen as soon as possible and be observed for signs of inadequate breathing, which would necessitate assisted ventilations. Nonrebreathing masks can be intimidating to an older patient; they may want to remove the mask to answer your questions. If you remove the patient's glasses, replace them once you have

applied the mask. If the patient cannot tolerate a nonrebreathing mask, use a nasal cannula. Some older patients with COPD may be on home oxygen. Many of these patients will medicate themselves. Medications taken prior to your arrival may affect your treatment, so gather this important information, if possible.

Words of Wisdom

Apply oxygen to patients experiencing dyspnea prior to asking questions.

Asthma

Asthma is a common disease among older adults. Onset can occur in old age with presenting symptoms of shortness of breath (especially with effort), chronic or nocturnal cough, and wheezing. Patients with asthma that is worsened by exertion may find that they are more susceptible to asthma attacks as they age.

Management of asthma in the geriatric population is similar to that in other age groups, although when asthma and cardiac disease coexist, the administration of preferred beta-adrenergic agents for asthma may exacerbate cardiac symptoms. Asthma clinical practice guidelines are the same for younger and older patients (**FIGURE 37-8**). On rare occasions,

FIGURE 37-8 A patient experiencing an asthma attack may have a bronchodilator medication in a metered-dose inhaler. An older patient may need assistance with the use of an inhaler.

© Jones & Bartlett Learning.

epinephrine may be indicated for a life-threatening asthma exacerbation. See Chapter 17, *Respiratory Emergencies*, for more information about asthma.

Pneumonia

Older patients with pneumonia often do not have the classic presentation of chills, fever, and productive cough. Instead, these symptoms are often supplanted by acute confusion (delirium), normal temperature, and a minimal to absent cough. The patient will often have flulike symptoms: exertional dyspnea, chest pain or discomfort, nausea and vomiting, muscle aches and pains, weight loss, wheezing, headache, and confusion.

The patient may exhibit signs of dehydration, including poor skin turgor, furrowed tongue, dry mucosa, tachycardia, and hypotension. This patient may be pale, with hot, dry skin caused by dehydration and an elevated temperature. Breath sounds range from diminished to wheezing, crackles, or rhonchi, and the chest may be dull to percussion. Assess for orthostatic changes and monitor oxygen saturation.

Prehospital treatment is supportive and includes oxygen to relieve dyspnea with appropriate adjuncts and IV access and fluid as indicated. The patient may benefit from application of continuous positive airway pressure (CPAP). Reassure the patient and keep the patient warm without overheating and increasing the patient's temperature. The receiving facility staff will determine whether antibiotics are necessary.

Pulmonary Embolism

Many pulmonary emboli are silent or present with tachypnea alone; that is, the classic triad of a sudden onset of dyspnea, chest pain, and hemoptysis is often altered or absent. If you suspect a pulmonary embolus, check for swelling, erythema, and warmth or tenderness of the lower leg; all are signs of a deep vein thrombosis, which is a common cause of pulmonary embolus. If deep vein thrombosis might be present, handle the leg gently and monitor the patient for respiratory changes.

Other symptoms associated with an embolism include syncope, fatigue, fever, anxiety, and/or cardiac arrest. The patient may present with tachycardia, wheezes, crackles, diminished breath sounds on the affected side, low oxygen saturation, and/or hypotension.

Prehospital treatment is largely supportive after ensuring that airway and ventilation are adequate. Rapid transport with oxygen and a position of comfort are the best treatment. Because aggressive airway management may be needed, call early for paramedic backup. Reassess the patient frequently during transport.

Assessment and Management of Cardiovascular Emergencies

As in all prehospital emergencies, health care providers must prioritize the patient's airway, breathing, and circulatory status during cardiovascular emergencies. Use the appropriate oxygen delivery device and airway adjunct consistent with the patient's condition. Remember to reassess the patient often.

Remember the changes that occur with aging or with ingestion of certain medications when you are assessing a geriatric patient. You may note peripheral edema that is chronic or changes in circulation strength and rate. The skin may be pale and diaphoretic and breath sounds may be decreased or unusual. The next sections discuss specific cardiovascular emergencies and their assessment and treatment.

Syncope

You should always assume that syncope, or fainting, in an older person is a life-threatening problem until proven otherwise. Syncope is the result of a temporary interruption of blood flow to the brain. Syncope has many causes, some more serious than others. Regardless, an older person who has experienced a loss of consciousness should be transported to the hospital and examined to determine the cause. **TABLE 37-2** shows some of the causes of syncope in an older patient.

Chest Pain

As mentioned previously, older patients may experience and present with chest pain differently than the general population. An older person experiencing an MI may only report dyspnea, weakness, or syncope, or there may be no associated pain. Remember that the pain threshold of older

TABLE 37-2 Possible Causes of Syncope in an Older Patient

Cause	Mechanism
Cardiac dysrhythmias/myocardial infarction	The heart is beating too fast or too slow, the cardiac output drops, and blood flow to the brain is interrupted. A myocardial infarction can also cause syncope.
Vascular and volume	Medication interactions can cause venous pooling and vasodilation (widening of a blood vessel), resulting in a decrease in blood pressure and inadequate blood flow to the brain. Another cause of syncope can be a decrease in blood volume because of hidden bleeding from a condition such as a leaking aortic aneurysm.
Neurologic	A transient ischemic attack or a "small stroke" can sometimes cause syncope.

© Jones & Bartlett Learning.

patients may be different. The OPQRST-I mnemonic for pain in the older patient is important. If the patient has a history of angina, determine if this episode is different from previous events. Is the patient taking the medication that is prescribed for the condition? Often, the patient will not use the term *pain*, but may use the word *discomfort* or *fluttering*.

Instead of asking about pain, say, "Describe to me exactly how you feel." The patient may respond negatively about any pain, but may be experiencing tightness or fullness in the chest, dyspnea, palpitations, or other symptoms.

Prehospital treatment for chest pain remains essentially unchanged in older patients, albeit with extra precautions because of the increased potential for medication side effects. Nitroglycerin may produce more hypotension in older patients than in younger patients or may react adversely with long-term medications. Aspirin may increase bleeding in a patient who is already taking anticoagulants. Additional treatments by prehospital providers should include close monitoring of fluids and avoidance of excessive fluid overload.

Myocardial Infarction

The classic symptoms of an MI, or heart attack, are often not present in older people. Some experience silent MIs, in which the usual chest pain is not present. **TABLE 37-3** shows signs and symptoms that are commonly noted in older patients who are experiencing an MI. The patient may also complain of epigastric or abdominal pain along with nausea, vomiting, and weakness. Treatment of MI is discussed in Chapter 18, *Cardiovascular Emergencies*.

Words of Wisdom

If the patient is hypotensive and is wearing a nitroglycerin patch, remove it. The patient's issue could be caused by too much of this medication.

Heart Failure

People 65 years and older are in a high-risk group for heart failure.²³ Cardiovascular diseases are the most common reason for hospitalization in the geriatric population.²⁴ Heart failure increases with age because of the associated risk factors, such as hypertension and coronary artery disease. Other risk factors for heart failure include sex, ethnicity, family history and genetics, long-term alcohol abuse, and multiple medical conditions, including coronary artery disease, emphysema, hyperthyroidism, thiamine (vitamin B) deficiency, and

human immunodeficiency virus infection.^{23,25} As with acute coronary syndrome, prevention is aimed at lifestyle changes: cessation of tobacco use, eating a healthy diet, control of blood glucose levels (in patients with diabetes), exercise, weight control, and control of hypertension.

Acute exacerbation of heart failure results in pulmonary edema that decreases the ability of the lungs to exchange gases. It may present with dyspnea or orthopnea. Because of the decreased oxygenation of all organ systems, including the brain, mental status changes may also be seen in acute exacerbation of heart failure, including a sensation of air hunger, or the perception that the person cannot take deep enough breaths to get enough air. Peripheral edema may also indicate worsening heart failure, although in the absence of other more serious symptoms, it may also be the result of any number of other circulatory, integumentary, or infectious conditions.

You should pay close attention to the position in which the patient with heart failure is found. When assessing for peripheral edema, the ankles are the logical site for evaluation. Because edema is likely to be formed in the lowest point to the ground on the patient's body, those patients who are confined to bed may present instead with **sacral edema**, edema that presents around the sacral region of the spinal column.

The presentation of heart failure in an older person can be masked by symptoms and signs

TABLE 37-3 Common Signs and Symptoms of MI in an Older Patient

Signs/Symptoms	Potential Causes
Dyspnea	Dyspnea, the feeling of shortness of breath or difficulty in breathing, is a common symptom in older people and is commonly associated with an MI. Dyspnea is often combined with other symptoms, such as nausea, weakness, and sweating. In older persons, chest pain is often not present, but dyspnea on exertion is noted.
Generalized weakness	Generalized weakness (malaise) can be caused by many things. However, you should suspect an MI in a patient with a sudden onset of weakness. Weakness is often associated with sweating.
Syncope/confusion/altered mental status	Syncope can have many causes, and in older people, none of these causes should be presumed to be minor. Syncope often has a cardiac cause. Altered mental status is usually a signal of poor blood supply to the brain, often from a cardiac dysrhythmia and MI.

Abbreviation: MI, myocardial infarction

symbolic of old age and shared by several chronic diseases—for example, dyspnea on exertion, easy fatigability (especially with left-side heart failure), confusion, crackles on lung exam, orthopnea, dry cough progressing to productive cough, and dependent peripheral edema in right-side heart failure. Acute exacerbations of heart failure are often related to poor diet, medication noncompliance, onset of dysrhythmias such as atrial fibrillation, or acute myocardial ischemia.

Prehospital treatment is unchanged from that of younger patients, although greater consideration is given to becoming familiar with the patient's medications and their implications for your proposed treatment. End-tidal carbon dioxide (ETCO₂) levels should be evaluated immediately and monitored throughout transport. Additional treatments by prehospital providers should include close monitoring of fluids and avoidance of excessive fluid overload, consideration of CPAP, and potential use of anticoagulation therapy in patients with atrial dysrhythmias to prevent thromboembolism.

Heart failure may also be exacerbated by fluid imbalances, particularly when overhydration occurs. Because the weakened and less-effective heart is not able to adequately pump normal vascular volumes, an increase in volume within the vascular system may stress the heart further. IV fluids should be administered judiciously in patients with heart failure because even slight changes can result in substantial negative outcomes, and achieving an appropriate balance of fluid and electrolyte administration may be complicated when both dehydration and heart failure are present.

Dysrhythmias

Rhythm disturbances (dysrhythmias) of the heart occur when the electrical system controlling the heartbeat experiences an interruption or malfunction. These irregularities cause heartbeats that are too fast, too slow, irregular, or absent. Many people experience an occasional or harmless dysrhythmia that they may describe as a skipping, fluttering, or fast heartbeat. Dysrhythmias in older people are generally a result of age-related changes in the heart, existing cardiac disease, adverse drug effects, or a combination of these factors.

Atrial fibrillation (coming from the atria), which is the most common dysrhythmia among older

people, increases the risk of stroke and heart failure. The fibrillating atria allow stasis of the blood, thereby encouraging clot formation and increasing the chances that a clot fragment might travel to the brain and cause a stroke. Most of the blood in the atria enters the ventricles when the valves open, with the remaining 20% being kicked in by contraction of the atria. The aging heart may function adequately when the preload provided by the atria ends up in the ventricles; however, when that 20% remains in the atria, new signs or symptoms of heart failure may develop or stable heart failure may decompensate.

Bradycardias are also more common in older people. The aging conduction system may produce sinus dysrhythmias such as sick sinus syndrome and atrioventricular blocks. Medications such as beta-blockers or calcium-channel blockers can cause excessive slowing of the heart. Even seemingly benign conditions, such as constipation, can result in bradycardia, particularly when the patient strains to have a bowel movement. Persistent bradycardias are often addressed with an internal pacemaker.

Hypertension

More than one-half of all older persons are hypertensive.²⁶ Most have isolated systolic hypertension resulting from a loss of arterial elasticity. Controlling systolic and/or diastolic hypertension in older people helps prevent strokes and MIs. Geriatric hypertensive emergencies require a controlled decline in blood pressure that often cannot be achieved in the field. Prompt transport is essential for these patients.

Aneurysms

The incidence of aneurysm increases with age. An aneurysm is a weakness in any artery that produces a balloon defect, weakening the arterial wall. This weakness may be congenital (present at birth) or acquired. In the latter case, hypertension, atherosclerotic disease, and obesity are contributing factors to development of this defect. Life-threatening aneurysms can develop in the brain, chest, or abdomen. For example, a new headache or a change in chronic headache patterns may signal early cerebral bleeding from an aneurysm. Frequently, however, the first manifestation is a sudden, devastating stroke. Use of anticoagulants for the management

of cardiac disease increases the negative effects of an aneurysm by increasing the amount of time necessary for bleeding to stop. Preventive measures, such as proper diet, exercise, smoking cessation, and cholesterol control, aim to control the risk factors associated with hypertension and atherosclerotic diseases.

Thoracic aneurysms generally remain asymptomatic until they become large or rupture. Early symptoms may be related to compression by the aneurysm, such as difficulty swallowing or hoarseness from laryngeal nerve pressure. AAAs present typically with abdominal pain or possibly only with back pain. Asymptomatic thoracic and abdominal aneurysms that do not exceed a certain size and are not expanding are generally treated without surgery and are reassessed on a regular schedule. In an older patient with back pain, examine the chest and abdomen carefully. The treatment of abdominal emergencies is surgical, so early recognition, assessment, stabilization, and rapid transport to an appropriate medical facility are essential.

Traumatic Aortic Disruption

Traumatic aortic disruption or aortic dissection occurs when the inside wall of the artery becomes torn and allows blood to collect between the arterial wall layers. It may occur with trauma or sustained hypertension, particularly when an AAA is present. Dissection weakens the arterial wall, making it susceptible to rupture. A thoracic dissection, for example, can produce chest pain that is difficult to differentiate from cardiac ischemia. Therefore, it is helpful to obtain blood pressure readings in both arms in all patients with chest pain. A systolic blood pressure difference of 15 mm Hg or higher suggests a thoracic dissection.

Assessment and Management of Neurologic and Endocrine Emergencies

Delirium

In any patient with delirium, assess for recent changes in the patient's level of consciousness or orientation. Specifically, look for an acute onset of anxiety, an inability to think logically or maintain attention, and an inability to focus. Also assess

for changes in vital signs, temperature (indicating infection), glucose level, and medications—all frequent causes of delirium. Use the DELIRIUMS mnemonic to identify other causes of delirium:

- **D**rugs or toxins
- **E**motional (psychiatric)/electrolyte imbalance
- **L**ow Pao₂ (carbon monoxide poisoning, COPD, heart failure, acute coronary syndrome, pneumonia)
- **I**nfection (pneumonia, UTI, sepsis)
- **R**etention of stool or urine
- **I**ctal (seizures)
- **U**ndernutrition or underhydration
- **M**etabolism (thyroid or endocrine, electrolytes, kidneys)
- **S**ubdural hematoma

Treatment of patients with delirium is mostly supportive. Monitor vital signs, including breath sounds. Use airway adjuncts if the patient is unable to maintain the airway, and obtain IV access to use as a fluid resuscitation route if needed.

Stroke

Stroke (cerebrovascular accident) is a leading cause of death in older people.⁵ The likelihood of experiencing a stroke becomes greater as a person gets older. The major risk factors include hypertension, diabetes, cardiac diseases (such as coronary heart disease, cardiomyopathy, heart failure, and atrial fibrillation), smoking, personal or family history of stroke or transient ischemic attack (TIA), and brain aneurysms.²⁷ Also of consideration are alcohol and illegal drug use, obesity, stress, high cholesterol levels, an unhealthy diet, and the use of NSAIDs.²⁷

Signs and symptoms of stroke include acute altered level of consciousness; numbness, weakness, or paralysis on one side of the body; slurred speech; difficulty speaking (aphasia); visual disturbances; headache and dizziness; incontinence; and, in the worst cases, seizure.

Hemorrhagic strokes, in which a ruptured vessel causes bleeding into the brain, are less common and more likely to be fatal. Ischemic strokes occur when a clot blocks the flow of blood to a portion of the brain. Brain tissue distal to this clot is deprived of oxygen and will die if the clot is not removed.

Effective prehospital acute stroke care includes early recognition, discovery of conditions that mimic strokes (such as hypoglycemia or hypoxia),

and timely transport to the most appropriate facility. Use a stroke assessment tool as appropriate, accounting for the patient's history when you are evaluating the components of the scale. An older person with severe arthritis may not move as well on one side, or damage from a previous stroke may make the person's speech difficult to assess. Always ask family or caregivers for information that may help you identify deviations from the patient's normal pattern of behavior or activity.

The treatment goal is to salvage as much of the surrounding brain tissue as possible. Many communities now have stroke centers that specialize in fast, effective treatment of stroke. Determining the onset of the symptoms of stroke is important. If the symptoms occurred within the past few hours, the patient will be a candidate for stroke center therapy and has a higher chance for recovery. Because time is of the essence, question bystanders about the last time the patient appeared "normal," and include this information in your documentation. See Chapter 19, *Neurologic Emergencies*, for information on assessment and treatment of stroke patients.

Transient Ischemic Attack

TIA's, also called ministrokes, entail a temporary disturbance of blood supply to the brain that results in a sudden, temporary decrease in brain function. The symptoms are the same as those for a stroke but generally last less than 24 hours; they are warning signs of a future stroke. Although a TIA results in no lasting damage to the brain, the gravity of this condition should not be minimized in the field. Because of the short amount of time that you often have with your patient, you most likely will not be able to determine whether the patient is experiencing a stroke or a TIA; therefore, all patients experiencing strokelike symptoms should be treated as though they are having a stroke. Furthermore, patients who report a history of previous TIA's should be considered at a much higher risk of having a stroke instead of another TIA.

Neuropathy

Your patient could be experiencing a **neuropathy**, a disorder of the nerves of the peripheral nervous system in which function and structure of the peripheral motor, sensory, and autonomic neurons

are impaired. Symptoms depend on whether the nerves affected are motor, sensory, or autonomic and where the nerves are located.

- Motor nerves: muscle weakness, cramps, spasms, loss of balance, and loss of coordination
- Sensory nerves: tingling, numbness, itching, and pain; burning, freezing, or extreme sensitivity to touch
- Autonomic nerves: affect involuntary functions that could include changes in blood pressure and heart rate, constipation, and bladder and sexual dysfunction

Neuropathies are treated with medication and other therapies not available in a field setting. You should make your patient as comfortable as possible and transport.

Altered Mental Status

Altered mental status is a symptom, not a disease. Consequently, the assessment and subsequent management of its numerous causes are complicated. Confused or disoriented patients make poor historians. In addition, they may be unable to speak and follow commands, making assessment extremely difficult. Always consider brain or head injury (medical or traumatic), tumors, emotional disorders, eye or ear problems, heart rhythm disturbances, dementia, medications, fluid balance changes (such as blood loss), respiratory disorders (such as hypoxia), endocrine changes (such as blood glucose level fluctuations), hyperthermia or hypothermia, and infection. Most important, prehospital providers need to consider neurologic causes (such as Alzheimer disease, Huntington disease, and Parkinson disease) and endocrine changes (such as diabetes).

An altered mental status is not normal. You need to rapidly determine if this patient requires immediate transport. When you are assessing a patient with signs of altered mental status, it is important to determine the onset of symptoms. Ascertain what is normal for this patient and whether the patient has a pertinent history that may be attributed to the problem. If the patient has diabetes, have the appropriate medications been taken? Is it possible the patient may have taken the wrong medication or taken alcohol with medications? Because of cost concerns, many older patients will try medications

that are not prescribed for them. They may be taking a medication that is prescribed for a spouse who has a similar problem, or worse, a completely different problem.

Potential causes of altered mental status can be remembered using the VITAMINS C & D mnemonic:

- **Vascular:** stroke, brain, embolism
- **Inflammation:** inflammation of the blood vessels in the brain
- **Toxins:** carbon monoxide poisoning
- **Trauma:** concussion, intracerebral hemorrhage
- **Tumors:** primary brain tumor or metastasis (developed elsewhere and spread to the brain)
- **Autoimmune:** production of immune system components against a normal structure in the body
- **Metabolic:** liver or renal failure, hypoglycemia, hyperglycemia, hypothyroidism or hyperthyroidism, HHNS
- **Infection:** meningitis, encephalitis
- **Narcotics and other drugs:** many possibilities, with a higher chance of mental status changes if preexisting CNS disease exists
- **Systemic:** sepsis, hypoxia
- **Congenital:** seizures
- **Degenerative:** Alzheimer disease and other dementias, Parkinson disease

Diabetic Disorders

Among people older than 65 years, one of every four in the United States has diabetes mellitus, primarily type 2 diabetes (formerly called adult-onset or non-insulin-dependent diabetes mellitus).²⁸ Type 1 diabetes has historically been referred to as insulin-dependent diabetes mellitus or juvenile diabetes, because it generally affects children. Many normal changes of aging contribute to the development of diabetes. The most common risk factor for this disease is having more than one chronic disease, and many older people with diabetes also have hypertension, heart disease, and stroke. Other risk factors for diabetes include a family history of diabetes, genetics, age, diet, obesity, and a sedentary lifestyle. Management of diabetes is complicated when other acute diseases are present, particularly infections; because older adults are more likely to have several comorbid disorders, management is especially complicated for them.

In the emergency setting, diabetes can result in two life-threatening conditions: hypoglycemia and hyperglycemia. Normal blood glucose levels range from approximately 70 to 120 mg/dL. Hypoglycemia occurs when blood glucose levels drop below the normal range, and hyperglycemia occurs when blood glucose levels exceed 120 mg/dL.

Geriatric patients with diabetes are at increased risk for hypoglycemia for several reasons: confusion about medication doses or usage, inadequate or irregular dietary intake, inability to recognize the warning signs because of cognitive problems, and/or blunted warning signs. Delirium may be the only indication of hypoglycemia in a geriatric patient. Other symptoms include mental status changes and confusion, diaphoresis, and decreased respiratory effort.

Symptoms of an elevated blood glucose level (hyperglycemia) include fatigue, poor wound healing, blurred vision, and frequent infections. Other symptoms of chronic hyperglycemia include the three Ps: polyuria (excessive urine output), polydipsia (excessive thirst), and polyphagia (excessive eating). New-onset diabetes in geriatric patients is often a mild progression that produces no symptoms.

Assessment of hyperglycemia and hypoglycemia is complicated by many of the changes associated with aging. Particularly, changes in peripheral vascular function make assessment of skin condition for key signs of hypoglycemia much more difficult because many older patients may be paler and cooler at baseline. Diaphoresis may also be less prominent as a result of changes in regulatory mechanisms and secretory functions of the skin. Baseline alterations of mentation may also be confused with acute mental status changes that are related to either hyperglycemia or hypoglycemia.

You should ensure that all vital signs, including blood pressure, blood glucose levels, temperature, and distal pulses, are assessed every 15 minutes and monitored for changes. Capnography, if available, should be used throughout the transport to monitor ET_{CO₂} as well as ventilatory status. Whereas Sp_{O₂} is a valuable tool, poor perfusion may make it difficult to obtain an Sp_{O₂} reading.

Treatment of diabetic emergencies in geriatric patients is no different than treatment in other populations, although care with fluid resuscitation and electrolyte balance is particularly important.

Prevention of type 2 diabetes is aimed at lifestyle changes that include dietary restrictions, exercise, and controlling obesity. Long-term management may include limiting of carbohydrate intake and the use of insulin and oral antihyperglycemic agents. Diabetes management also focuses on preventing many of the devastating systemic effects of the disease, including aggressive wound management, frequent screening for impaired renal function, and management of pain associated with neuropathy.

Hyperosmolar Hyperglycemic Nonketotic Syndrome

Older people with diabetes and consistently high blood glucose levels are more susceptible to HHNS than DKA. DKA is a life-threatening condition that is associated predominantly with type 1 diabetes (patients who have this condition tend to be young—teenagers and young adults). See Chapter 21, *Endocrine and Hematologic Emergencies*, for more information on this condition.

The most frequent cause for HHNS is infection. Other potential risk factors include hypothermia, hyperthermia, cardiac disease, pancreatitis, and stroke. The patient is likely to present with hyperglycemia that is generally greater than 600 mg/dL and has acute confusion with dehydration, although signs of dehydration may be altered in older adults (**TABLE 37-4**). With HHNS, hyperglycemia and hyperosmolarity result in osmotic diuresis and an osmotic shift of fluid to the intravascular space, resulting in further intracellular dehydration. Signs and symptoms include dizziness, confusion, altered mental status, and polydipsia.

Prehospital treatment of HHNS in younger and older patients is the same; however, the systems of older patients may be less tolerant of aggressive

fluid therapy. Airway management is the top priority. Use appropriate airway adjuncts and consider calling for paramedic backup if endotracheal intubation is indicated. Spinal motion restriction should be used for all unresponsive patients found down, unless witnesses can validate that no fall occurred. Treat for shock as indicated. Large-bore IV access should be gained as soon as possible, but do not delay transport while initiating the IV line. Also, obtain a blood glucose level as soon as possible.

A 20-mL/kg bolus of 0.9% normal saline is appropriate for nearly all adults who are clinically dehydrated. In patients with a history of heart failure and/or renal insufficiency, give fluid sparingly and auscultate breath sounds frequently. If the glucose level is less than 70 mg/dL and the patient is symptomatic, administer supplemental dextrose either orally or intravenously depending on level of consciousness and local protocols, as soon as possible.

Thyroid Disorders

As mentioned previously, thyroid abnormalities become more common with age, with diagnosis often occurring via a routine blood testing. Adult hypothyroidism (myxedema) is manifested by a general slowing of the body's metabolic processes as a result of the reduction or absence of thyroid hormone. Signs and symptoms may be attributed to normal aging: cold intolerance, constipation, dry skin, weakness, and weight gain. Prior thyroidectomy is also more common in geriatric patients, who typically take synthetic thyroid hormones.

The presentation of acute-onset hyperthyroidism (thyrotoxicosis) may be more difficult to detect in older people; tachycardia is generally present, but signs such as tremor, anxiety, or hyperactive reflexes may be missing. Atrial fibrillation is more likely to be induced by an overactive thyroid gland in a geriatric patient. A smaller percentage of older patients with hyperthyroidism present with symptoms opposite of those expected: weakness, lethargy, and depression.

Patients with hyperthyroidism or hypothyroidism are likely to require supplemental oxygen. Hypoglycemia may need correction with supplemental dextrose. Hypothyroid conditions may result in diminished respiratory effort that may require positive-pressure ventilation.

TABLE 37-4 Signs of Dehydration in Older Adults

- Dry tongue
- Longitudinal furrows in the tongue
- Dry mucous membranes
- Weak upper body musculature
- Confusion
- Difficulty in speech
- Sunken eyes

Continued decrease of hormone levels may result in myxedema coma, an extreme manifestation of hypothyroidism that is accompanied by physiologic decompensation. Myxedema coma is more likely in women than in men and occurs primarily in the geriatric population.²⁹

See Chapter 21, *Endocrine and Hematologic Emergencies*, for more information on thyroid disorders.

Assessment and Management of GI Emergencies

Several life-threatening abdominal problems are common in older patients. Remember that internal bleeding may be a cause of the patient's abdominal problem, which can result in shock and death.

Abdominal Pain

Constipation is a frequent and substantial problem in older people. Although it can cause acute abdominal pain, it should not be the initial condition suspected when a patient experiences such discomfort. Instead, causes with high mortality, such

as bleeding from an acute abdominal aneurysm or dead bowel from mesenteric ischemia, should be investigated first. In your assessment of a gastric emergency, ask the patient about food and fluid intake, history of abdominal issues, current bowel and bladder habits, and medications and supplements before proceeding with a physical exam.

The geriatric patient who reports abdominal pain may be among the most frustrating patients because it will be difficult to determine the cause of the pain. Many older patients presenting with abdominal pain will require hospital admission, and some will need surgical intervention. The history of acute versus chronic pain may help in your assessment, and the mnemonic OPQRST-I for pain may help you determine what is happening to your patient. There are numerous causes of acute abdominal pain in the geriatric population, including inflammation, infection, and ischemic disorders. The patient may have a difficult time localizing the pain and describing whether the pain is radiating or referred. Symptoms are often vague and manifest only as diffuse abdominal pain with no specific point of origin. Abdominal and gastric problems often require surgical treatment, so early recognition

YOU are the Provider

Part 4

Your partner arrives with the stretcher. You place the patient on the stretcher and secure him with all straps. After the stretcher is secured inside the ambulance, you instruct your partner to drive emergently to the local hospital, approximately 12 minutes away. En route to the hospital, you elect to administer a second 250-mL fluid bolus to increase the patient's blood pressure based on persistent hypotension. Approximately 6 minutes from the hospital, the patient vomits what appears to be 200 mL of coffee-ground emesis. You ensure that the airway is clear, carefully position the patient on his left side, and call your report in to the ED. On arrival at the hospital, you turn over care to the waiting ED staff without further incident.

Recording Time: 20 Minutes

Respirations	26 breaths/min, normal
Pulse	Slow and thready, 68 beats/min
Skin	Cool, pale, and clammy
Blood pressure	78/42 mm Hg
Oxygen saturation (SpO₂)	100% on 15 L/min via a nonrebreathing mask
Pupils	PERRLA

7. What are the potential hazards of the patient vomiting?
8. Why should lactated Ringer solution be avoided in this patient?

and rapid transport for definitive hospital care are the best practice. If you suspect an AAA, treat the patient for shock if evident and provide prompt transport to the hospital.

GI Bleeding

GI bleeding also becomes more common with age, and it is almost always the result of either physiologic changes that lead to an increased likelihood of bleeding systemically or pathologic processes that specifically affect the digestive system. Several normal changes of aging increase the time needed to obtain hemostasis, including decreased vascular tone and thinning of various epithelial tissues. Decreased rates of peristalsis also increase the likelihood that irritating substances will damage the gastric lining. Older patients are also more likely to take medications that alter coagulation, including warfarin, aspirin, and heparin. Pathologic processes within the GI system that are sometimes responsible for bleeding include ulcers and varices; cancers of the stomach, esophagus, colon, and rectum; diverticulitis; cirrhosis; and bowel obstructions.

Although the source of GI bleeding may vary, the signs and symptoms vary more by the location where the bleeding is noted. Bleeding from the esophagus is most commonly associated with varices and alcohol abuse; the patient will present with violent vomiting of emesis that contains almost no food and a large quantity of bright red, uncoagulated blood. Bleeding from the stomach may produce either red or darker coffee-ground emesis, and it is most commonly associated with peptic ulcer disease. Bloody stool usually indicates bleeding from the lower GI system, although blood from the stomach may be digested and appear as dark, tarry stool. Bright red blood in the stool usually comes from the large intestine or rectum and may be caused by diverticulitis, large bowel obstructions, anal fissures, or hemorrhoids. In general, the darker the blood, the longer it has been in the body, and, therefore, the further the distance between the site of bleeding and the portal of exit.

Upper GI hemorrhage occurs when bleeding occurs from the esophagus, stomach, or duodenum. When severe, this condition is a true medical emergency that must be recognized and assessed quickly. Not only are older people more susceptible to upper GI bleeding, they often need urgent

surgery and also are at a greater risk of complications and death.

It is not possible to determine the cause of upper GI bleeding without an endoscopic examination (inspection of the inside of a hollow organ or body cavity) of the esophagus, stomach, and duodenum. However, obtaining a thorough history can provide you with clues to the cause. Regular use of NSAIDs or alcohol may result in bleeding from irritation of the lining of the stomach or from ulcers (a hollowing out or disintegration of tissue) in the stomach or duodenum. Forceful vomiting can cause tears in the esophagus that result in bleeding. Cirrhosis of the liver from long-term alcohol use or chronic infectious hepatitis may cause enlargement of the veins (varices) in the esophagus. These varices can rupture and result in massive bleeding. Stomach cancer or esophageal cancer can also produce upper GI bleeding. Recent weight loss or difficulty swallowing would raise the suspicion of cancer as the source of bleeding.

Lower GI hemorrhage primarily describes bleeding from the colon and rectum and should never simply be attributed to hemorrhoids. Colon polyps and colon cancer are also possible causes, among others. Minor lower GI bleeding is characterized by small amounts of red blood covering formed brown stools or scant amounts of red blood noticed on the toilet paper. Severe lower GI bleeding is characterized by passing significant amounts of red blood or maroon-colored stools.

Assessment should begin with identifying risk factors such as a history of previous lower GI bleeding, symptoms or signs suggestive of colon cancer, recent constipation or diarrhea, and use of medications such as blood thinners. Treat for shock. Severe lower GI bleeding requires immediate transportation to the nearest ED.

Some signs and symptoms of GI bleeding are associated with hypovolemia that occurs from the blood loss. These include agitation, dizziness, syncope, hypotension, and changes in mental status. Others may be associated with the disease processes that caused the bleeding, including jaundice, hepatomegaly, constipation or diarrhea, pain with voiding, nausea, and abdominal pain.

When you arrive at the scene, it is more important for you to be able to assess the severity of the bleeding than to determine the cause of bleeding. Slower bleeding is characterized by emesis with

coffee-ground appearance. With minor bleeding, the pulse rate and systolic blood pressure are normal. Brisk bleeding presents with hematemesis (vomiting red blood) or melena (black, tarlike stools). Note that melena, not pain, is the most common presenting symptom of GI bleeding. Prehospital treatment is supportive.

Regardless of the cause of GI bleeding, treatment should be focused on recognition and management of hypovolemic shock and transport to a facility capable of providing definitive care; many patients with GI bleeding may require surgery to repair the site of injury or disease. Be cautious in fluid resuscitation and bear in mind that the older adult's compensatory mechanisms may be altered because of normal aging processes. Finally, keep in mind that these patients may be on blood-thinning medications (eg, warfarin) that prevent them from forming clots following major injuries.

Nausea, Vomiting, and Diarrhea

Nausea, vomiting, and diarrhea need to be investigated to determine the underlying cause. These issues may be attributed to conditions inside or outside the GI tract. If an older patient is complaining only of nausea, this does not mean that vomiting and/or diarrhea will not soon follow. Remember that nausea may be an older patient's problem during a cardiac episode. There are many possible causes of GI issues. During the assessment of the patient, determining the onset may provide a clue to possible causes. Viral gastroenteritis, which your patient may self-diagnose as stomach flu, is a common finding.

During your assessment of the patient who reports having nausea, vomiting, or diarrhea, remember to ask the color associated with the vomiting and/or diarrhea. Take note in your environmental assessment if there are basins or wastebaskets near the patient, and look inside to see any abnormal emesis or if it appears to be blood tinged. Bright red bleeding is not normal and must be noted in your report. As discussed, bloody emesis or diarrhea is a clinically important finding and may indicate serious GI bleeding.

Prepare for episodes of vomiting while assessing your patient and also during transport; ensure standard precautions, and have your suction ready. Many patients are unable to provide you any warning prior to vomiting.

Bowel Obstruction

Large-bowel obstructions in older people are likely to be caused by cancer, impacted stool, or sigmoid volvulus. In addition, small-bowel obstruction secondary to gallstones increases substantially with age. With one or more episodes of cholecystitis (inflammation of the gallbladder), the gallbladder adheres to the small bowel and, over time, creates an opening, or fistula. The stone or stones drop into the bowel and produce the obstruction. The large and small intestines are at risk for obstruction from adhesions due to previous surgery or infection or when a segment of bowel is forced into a fascial defect (hernia) in the abdominal wall.

Biliary Diseases

Along with implications for small-bowel obstructions, biliary diseases, including cirrhosis, hepatitis, and cholecystitis, may also present independently in older patients. Signs and symptoms of biliary disease include jaundice, fever, right upper quadrant pain with possible radiation to the upper back or shoulder, and vomiting or nausea. Jaundice may be more profound in paler patients because less melanin is present to interfere with visibility of bilirubin. Although these diseases cause fever, this response may be repressed in older patients. Pain sensation may be altered, as well, resulting in unusual referral paths or the absence of abdominal pain.

Pain management may be indicated for patients with acute cholecystitis; however, be cautious in administering opiates to older patients because their ability to compensate for cardiovascular and respiratory changes that may accompany these medications will be decreased.

Peptic Ulcer Disease

Older patients are more likely than younger ones to have stomach or duodenal ulcers (peptic ulcer disease). The main risk factors for peptic ulcers are regular use of NSAIDs and infection with *Helicobacter pylori* (an ulcer-associated bacterium of the stomach), both of which are more common in older patients. Other medications have also been implicated in ulcer formation. Social factors, such as high-stress professions, and certain personality types have also been associated with ulcer formation. The main symptom of peptic ulcer disease is dyspepsia (gnawing, burning pain in the upper

abdomen), which usually improves immediately after eating but returns several hours later. Other causes of dyspepsia include acid reflux, gastritis, and gastric cancer. Be aware that symptoms of chest pain due to dyspepsia and chest pain due to cardiac disease or acute MI are easily confused, especially in older patients with altered pain sensation.

Assessment and Management of Renal Emergencies

Urinary Tract Infections

UTIs are common in the older adult population.³⁰ UTIs usually develop in the lower urinary tract (urethra and bladder) when normal flora (the bacteria that naturally populate the skin) enter the urethra and grow. Although UTIs are usually more common in women due to the relatively short urethra and its proximity to the vagina and rectum, an increase in UTIs is seen in men older than 50 years because of obstruction of the urethra by the prostate. Common risk factors include diabetes, prostatitis, cystocele (prolapse of the bladder into the vagina), urethrocele (prolapse of the urethra into the vagina), kidney obstruction, and indwelling urinary catheters.

While you are performing a physical assessment, you may notice a fever, shortness of breath, GI symptoms, neurologic symptoms, poor urinary output, increased urinary frequency, and hematuria. These patients will report painful urination, frequent urges to urinate, and difficulty urinating. You should evaluate the patient's indwelling catheter, if applicable, for sediment, opacity, color, or presence of blood. A strong odor may be present. Later signs and symptoms may include hypotension, tachycardia, diaphoresis, and pale skin.

Renal Failure

Renal failure results from a decrease in the rate of filtration through the glomeruli, causing toxins to accumulate in the blood. If the kidneys are no longer able to excrete waste, concentrate urine, and control electrolytes, pH, or blood pressure, then renal failure develops. Risk factors for chronic renal failure include diabetes, cardiac disease, pyelonephritis, hypertension, autoimmune disorders, glomerulonephritis, and polypharmacy. Chronic renal failure may require lifelong dialysis (either hemodialysis

or peritoneal dialysis) or kidney transplantation. Hemodialysis is a process in which patients are attached to a hemodialysis machine for 3 to 4 hours three times per week so that the patient's blood can be filtered through the machine and waste can be removed.

Although dialysis treatments are generally considered to be basic life support nonemergency transport, if a patient misses a treatment, the situation can become an advanced life support emergency. Signs and symptoms of such an emergency include hypertension, headache, anxiety, fatigue, anorexia, vomiting, increased dark urination, altered mental status, and seizures. All vital signs should be monitored regularly; however, you should not obtain blood pressure readings on the same arm that has a fistula. Breath sounds should be monitored. The patient should be transported to a hospital that has hemodialysis capabilities. IV fluids should be administered to assist circulation as necessary.

Special Populations

The best dose of a drug for an older patient is the lowest dose that will achieve a therapeutic effect.

Assessment and Management of Toxicologic Emergencies

The most common therapeutic error in cases of reported poison exposure occurs when a patient inadvertently takes or is given medication twice, which is called “double dosing.” Essentially, medications are poisons with beneficial side effects. Noncompliance of medication (not taking the medication in the prescribed dose) also may cause an emergency, as discussed earlier.

Another factor contributing to the toxic effects of drugs in older people is alterations in pharmacokinetics related to aging (that is, the absorption, distribution, metabolism, and excretion of drugs). Decreases in kidney function and GI absorption further increase susceptibility to toxicity. Pharmacokinetics may also be influenced by diet, smoking, alcohol consumption, and use of other drugs. Medications such as digoxin that depend on the liver and kidney for metabolism and excretion are particularly likely to accumulate to toxic levels in older patients. With most medications, we know little about

FIGURE 37-9 The toxic effects of drugs may initially manifest in the form of confusion.

© Jones & Bartlett Learning.

the optimal dosage for older people because almost all clinical trials to establish the safe dosages of medications are performed in young populations. For the most part, dosages for older people need to be reduced compared with those for younger patients. (“Start low, go slow.”)

Although almost any medication can produce toxic effects in an older person, certain medications and classes of drugs are implicated more often than others. Typically, toxic effects present with psychiatric symptoms (such as hallucinations, paranoia, delusions, agitation, and psychosis) and cognitive impairment (such as delirium, confusion, disorientation, amnesia, stupor, and coma) (**FIGURE 37-9**).

Drug and Alcohol Abuse

Many geriatric patients see multiple physicians for various disorders that may include pain management and/or require sedation. Some states have instituted a statewide system to control and monitor scheduled medication distribution, which is then used by all pharmacies in the state. These measures help prevent the same medications being prescribed by multiple physicians. However, it does not prevent taking subsequent doses of the same medication.

Substance abuse among older adults is often in response to a life-changing event such as the loss of a spouse, declining health, or low self-esteem. The prevalence of alcohol and drug misuse among older people is also attributable to the multiplicity of medications that are prescribed for them and their heightened vulnerability to abuse owing to

the effects of aging. Decreased body mass and total body water means higher concentrations of blood alcohol compared with consumption of the same amount of alcohol by younger adults; at the same time, the combination of digestive, renal, and hepatic system changes results in slower elimination of alcohol from the older adult’s body.

As the geriatric population continues to grow and experiences even more chronic disabilities, the likelihood of substance abuse–related problems in this group will increase. Recognizing substance abuse in older people can be difficult. If they have engaged in this behavior for a long time, it may be well hidden from, or even accepted by, family and friends. Because substance abuse can complicate your field assessment and treatment, it is important to ask about this issue.

Geriatric Trauma Emergencies and Management

Unintentional injury is the seventh leading cause of death in people 65 years and older in the United States.⁵ Several factors place an older person at higher risk of trauma than a younger person, such as slower reflexes, visual and hearing deficits, equilibrium disorders, and an overall reduction in agility. In particular, changes in the body’s homeostatic compensatory mechanisms combined with the effects of aging on body systems and any preexisting conditions usually add up to less favorable outcomes in trauma situations. Compensation in trauma is successful when an increased pulse rate, increased respirations, and adequate vasoconstriction make up for trauma-related blood loss. In contrast, reduced cardiac reserve, decreased respiratory function, impaired renal activity, and ineffective vasoconstriction may result in unsuccessful recovery from traumatic situations. Furthermore, an older adult is more likely to sustain a serious injury in a trauma situation because stiffened blood vessels and fragile tissues tear more readily, and brittle, demineralized bone is more vulnerable to fracture. A decreased ability to thermoregulate and a limited tolerance of thermal extremes also make a geriatric patient more susceptible to hypothermia.³¹

Most geriatric trauma cases involve falls or motor vehicle crashes. Although most falls do not produce serious injury, they do result in increased mortality in geriatric patients—a trend that is

directly related to the patient's age, preexisting disease processes, and complications related to the trauma. Falls are associated with a higher incidence of anxiety and depression, a loss of confidence, and postfall syndrome. In postfall syndrome, geriatric patients develop a lack of confidence and anxiety about potential falls.

Words of Wisdom

Compensatory mechanism changes + aging systems + preexisting conditions = bad outcomes.

Falls among older adults are divided between those resulting from extrinsic (external) causes, such as tripping on a loose rug or slipping on ice, and those resulting from intrinsic (internal) causes, such as a dizzy spell or a syncopal attack (**TABLE 37-5**). The risk of falls increases in people with preexisting gait abnormalities (such as from neurologic or musculoskeletal impairment) and cognitive impairment. Older patients with osteoporosis have lower-density bones, so even a sudden, awkward turn may fracture a bone.

When you are treating a patient who has fallen, you need to obtain a careful history. Although the patient often attributes the fall to an accidental cause ("I must have tripped over the rug."), meticulous questioning often reveals a period of dizziness or palpitations just before the fall, suggesting a different cause.

Home safety assessments by EMS—during a routine visit or as part of an outreach program—may reduce fall incidence. Components of this assessment should include clear pathways to and from the bathroom, handrails in bathtubs and on steps, no loose rugs or other objects on the floor, wheelchair ramps with grip tape, and caregivers who are trained to lift and move patients.

After falls, motor vehicle crashes are the second leading cause of accidental death from injury among older adults.³² An older patient is far more likely than a younger patient to be fatally injured in a motor vehicle crash,³³ even though excessive speed is rarely a causative factor in the older age group. Impaired vision, errors in judgment, and underlying medical conditions contribute to the higher risk. Impairments in vision and hearing,

TABLE 37-5 Causes of Falls in Older Adults

Cause	Clues That Suggest This Cause
Extrinsic (mechanical)	Obvious environmental hazard at the scene, such as poor lighting, scatter rugs, uneven sidewalk, or ice or another slippery surface
Intrinsic (internal causes)	Sudden fall; patient found on the ground somewhat confused, often temporarily paralyzed and unable to get up; no premonitory symptoms
Postural (orthostatic) hypotension	Fall when getting up from a recumbent or sitting position (Check medications the patient is taking, and ask about occult blood loss, such as presence of black stools. Measure blood pressure in recumbent and sitting positions.)
Dizziness or syncope	Marked bradycardia or tachydysrhythmias
Stroke	Other characteristic signs of stroke, such as hemiparesis, hemiplegia, or aphasia
Fracture	Patient reports feeling something snap before falling—this is extremely rare and often associated with preexisting bone abnormality such as a tumor or prior fracture.

© Jones & Bartlett Learning.

along with diminished agility, also contribute to pedestrian deaths involving older adults.

Pathophysiology of Trauma

Consider the aging body's decreasing ability to isolate simple trauma when you are assessing and caring for an older patient. An isolated hip fracture in a healthy 25-year-old is rarely associated with systemic decline. However, the same injury in an 85-year-old patient can produce a systemic effect that results in deterioration, shock, and life-threatening hypoxia or multiple end-organ system failure, a dangerous condition in which the body tissues and cells do not have enough oxygen.

Although an injury may be considered isolated and not alarming in most adults, an older patient's

overall physical condition may decrease the body's ability to compensate for the effects of even simple injuries. Younger patients have the capability to increase their heart rate, constrict their blood vessels, and breathe faster and deeper to compensate for injuries. The aging body has a heart that can no longer beat as fast, vessels that cannot constrict as well because of atherosclerosis, and lungs that do not exchange oxygen as well.

Older patients have reduced stroke volume along with potential dysrhythmias, decreased respiratory function, a decrease in chest wall compliance, a decrease in ciliary action to remove secretions, impaired renal activity, ineffective vasoconstriction, and a reduction in neuron mass and velocity of impulses. These factors make it more difficult for an older patient to recover from a traumatic situation.

As the brain shrinks, there is a higher risk of cerebral bleeding following head trauma. Because brain tissue atrophies with age, older persons are more likely to sustain closed head injuries, such as subdural hematomas, in trauma situations. These hematomas can go unnoticed because the blood has a void to fill before it can produce pressure in the skull and, therefore, signs of head trauma. Geriatric female patients may have decreased bone mass and strength from osteoporosis, a generalized bone disease that is commonly associated with postmenopausal women; this can increase the likelihood of fractures, especially in the hip. In all older patients, the spine stiffens as a result of atrophy of intervertebral disks, and the vertebrae become brittle. Therefore, compression fractures of the spine also are more likely to occur in older patients.

Burns are a substantial risk of morbidity and mortality in older adults because of physiologic and pathophysiologic changes. Older people are more likely to experience burns because of altered mental status, inattention, and a compromised neurologic status. The risk of mortality is increased when preexisting medical conditions are present, the immune system is weakened, and fluid replacement is complicated by renal compromise. When you are assessing a burn patient, you need to monitor the patient's hydration status by assessing current vital signs, mucous membranes, and urine output, which is typically 50 to 60 mL/h or 0.5 to 1 mL/kg/h for adults.

There is higher mortality from penetrating trauma in older adults, especially in the case of gunshot wounds. Penetrating trauma can easily cause serious internal bleeding. An older patient's limited physiologic reserves and more subtle presentation can affect proper management and transportation options.

Internal temperature regulation is slowed in older adults and continues to slow with increasing age. The body's ability to recognize fluctuations in temperature becomes delayed owing to a slowed endocrine system. Heat gain or loss in response to environmental changes is delayed by atherosclerotic vessels, slowed circulation, and decreased sweat production in the skin. In addition, thermoregulation can be adversely affected by chronic disease, medications, and alcohol use, all of which are more frequent in older adults.

Not surprisingly, older adults are at an increased risk of death from hypothermia, and most indoor hypothermia deaths involve geriatric patients.³⁴ Although living in an area with typically harsh winters is a risk factor, hypothermia can develop at temperatures above freezing when an older person is exposed to them for a prolonged period.

Providers should be aware of environmental emergencies during extreme heat and cold, particularly in lower socioeconomic areas that may not have sufficient heat or air conditioning. Managing such events may require public awareness and preplanning. You may have to keep the ambulance's patient compartment at a temperature that is higher than normal, and perhaps uncomfortable for you, to adequately maintain the geriatric patient's temperature.

Trauma in older adults can also be caused by abuse. Abuse comes in many forms and may include physical assault. Be aware of the environment and conditions that a patient lives in, and take note of soft-tissue injuries that cannot be explained by the person's lifestyle and physical condition. Patients

Words of Wisdom

When you respond to a motor vehicle crash, be alert to the possibility that a medical emergency may have caused the accident, especially in single-vehicle crashes with no apparent cause.

may be reluctant to talk about it. If you have any doubt that abuse is a consideration, submit an elder abuse report. Elder abuse is discussed in more detail later in this chapter.

Assessment of Geriatric Trauma

Scene Size-up

Trauma to an older person can be more debilitating than trauma to a younger person. Consider what may happen to the patient following trauma: bone fractures, recovery, and a possible nursing home stay. Was there an underlying medical cause that led to the traumatic event? Did the patient have a syncope episode before the fall or the motor vehicle crash?

As with all scenes, ensure your own safety first. Take standard precautions. Consider the number of patients, especially in the case of a motor vehicle crash. Determine if you need additional or specialized resources.

In an older person, decreased muscle mass in the abdomen can mask abdominal trauma. Consider the mechanism of injury and maintain a high index of suspicion.

Primary Survey

During the primary survey, address life threats. Determine whether this is a priority patient and to which facility the person will be transported. The decision that the patient has a potentially critical or life-threatening condition would limit on-scene treatment to that which is absolutely necessary for patient stabilization. Be conservative in your thinking. A geriatric patient who sustained a minor fall could have intracranial bleeding, especially if the patient drinks alcohol or is taking blood thinners. It is recommended that older trauma patients be transported to a trauma center regardless of the severity of obvious injuries.

The general impression is an important aspect of all patient assessment. As you approach the patient, you should be able to tell if the patient is generally in stable or unstable condition. You will

use this information to help you with your further assessment. The GEMS diamond, discussed earlier in the chapter, is also useful in the assessment of a geriatric trauma patient. Determining neurologic status may be difficult if you do not know the patient's baseline status. Try to get information from someone familiar with the patient, if possible. Use the AVPU mnemonic and the Glasgow Coma Scale to determine mental status. An important consideration with any patient is the inability to remember the event.

If the patient is talking to you, the airway is patent. Patients who have noisy respirations have airway compromise. Older patients may have a diminished ability to cough, so suctioning is important. Suction any blood or foreign material. Dentures should be left in place as long as they fit well because they provide shape and stability for the mouth, creating a better seal when ventilating a patient with a mask. However, loose dentures may create an airway obstruction. It is more difficult to ventilate a patient with no teeth.

In an unresponsive patient, open the airway with a modified jaw-thrust maneuver. Use an oropharyngeal or nasopharyngeal airway as appropriate, and ventilate with a bag-mask device if the patient's respiratory effort is inadequate or absent. Any curvature of the patient's spine will require padding to keep the patient supine and the airway open.

Breathing problems caused by trauma can be made worse by preexisting respiratory disease and the compromised respiratory effort that comes with aging. Remember that minor chest trauma can cause lung injury. Perform a thorough respiratory assessment and physical assessment of the chest, and treat accordingly. Monitor SpO_2 and maintain a high index of suspicion in a patient with chest trauma that can cause underlying lung injury. Keep suction readily available and wrap patients warmly to prevent hypothermia.

Manage any external bleeding immediately. Be suspicious of signs and symptoms of internal bleeding. The bodies of older people do not compensate for blood loss as well as the bodies of younger people do, and older patients can more easily go into shock. A head injury with minimal mechanism can cause cerebral bleeding. Drinking alcohol and taking anticoagulant medications can

worsen internal bleeding or make external bleeding more difficult to control. Also, remember that patients who were hypertensive prior to injury may have a normal blood pressure when they are actually in shock.

History Taking

When you are assessing a geriatric trauma patient, look for family members or bystanders who may be able to provide information about the patient's history. Because of alterations in mentation, an older patient may be a poor historian.

When called for a medical alert activation, find out if it is an inactivity alarm or a distress alarm. Consider who has a key to gain entry to check on the patient. Many times this may be the person who calls for assistance. Consider these factors if you have to force entry to check on the welfare of a patient. Responsibilities vary according to jurisdiction regarding who is allowed to force entry. Find out what laws and policies exist within your EMS system.

Medications taken for various medical conditions may affect coping mechanisms. Do not lower your index of suspicion when vital signs do not change as anticipated based on suspected injuries. Remember, changes in vital signs may be delayed in older patients. A lack of change may also be due to medications that the patient is taking.

Assessment of Falls

When you are assessing a patient who experienced a fall, always consider what factors may have contributed to the event (**FIGURE 37-10**). Did the patient wake up in the middle of the night to go to the bathroom and trip? Did the patient miss a step because of visual impairment? Many older patients will be able to tell you how many steps they have in their home. Counting the stairs as they ascend or descend may help them be more aware and in control of their body mechanics. Did the patient trip over a loose item such as a rug? Patients with walking assist devices also are susceptible to falls.

Try to determine how long the patient has been on the ground. Use your keen sense of awareness to investigate the surroundings and the potential mechanism of injury, especially if the patient is unable to recall the events that may have caused the

FIGURE 37-10 When you are assessing a patient for a fall, look for clues about what may have caused or contributed to the event.

© Alex Edelman/AFP/Getty Images.

fall. If you are called early in the morning and the previous night's dinner is still on the table, the patient may have fallen 12 to 16 hours earlier. Look for other clues such as mail and newspapers building up outside. Also consider the neighbors; although they can be a valuable source of information, you must be careful to maintain the patient's privacy.

Attempt to determine why the fall occurred. As mentioned, medical conditions such as syncope (fainting), a cardiac rhythm disturbance, or a medication interaction may lead to a fall that causes injury to the patient. Sometimes, a recent history of starting or stopping blood pressure medication is enough to cause a patient to become dizzy and fall. Look for clues from the patient, bystanders, and the environment. Although the trauma that the patient sustains from the fall can be serious, you should also consider that if a medical condition caused the fall, it could exacerbate, or be exacerbated by, the injury.

Secondary Assessment

The physical examination should be performed on a geriatric trauma patient in the same manner as for any adult but with consideration of the higher likelihood of damage from trauma. Remember that any head injury can be life threatening in an older adult. When you are examining the chest, consider that breathing may be impaired as part of the normal aging process. Check breath sounds, and look to see if there is any evidence of pacemakers or previous

cardiac surgery. Even though it may appear that the patient has only experienced trauma, keep in mind that this does not mean the person may not also be having medical problems. When you are assessing the abdomen, remember that older patients have a flaccid abdominal wall and may not present with pain and rigidity in the abdomen when trauma has been sustained. Decreased muscle size in the abdomen may mask abdominal trauma. Look for bruising and other evidence of trauma. Injury to the liver or spleen may present with diffuse abdominal pain, or pain may refer to the left shoulder.

Assess the pulse, blood pressure, and skin color and condition. Capillary refill is often unreliable in older people because of compromised circulation. Remember that some older people take beta-blockers, which will inhibit their heart from becoming tachycardic as you would expect in shock. Even a heart rate in normal ranges may be high for someone taking beta-blockers. Try to determine if the blood pressure is normal for that person. Remember that an older patient may have what appears to be a normal blood pressure but may still be in shock.

Reassessment

Reassessment of the primary survey, level of consciousness, vital signs, and interventions should be performed and documented as with any patient, but remember that a geriatric patient has a higher likelihood of decompensating after trauma. Be prepared.

Management of Geriatric Trauma

Broken bones are common and should be splinted in a manner appropriate to the injury. Because of the amount of flexion that occurs in the spinal column, hips, and knees of older patients, effective application of conventional splints and backboards to immobilize them may be difficult or impossible unless a large amount of padding is used. What is considered a normal anatomic position for children and adults is often abnormal for geriatric trauma patients. Do not try to force a patient with pronounced joint flexion or kyphosis into a normal anatomic position; this can be very painful and may cause further harm. Some devices, such as traction splints, simply do not work on patients with flexed

FIGURE 37-11 Vacuum mattresses that conform to body contours are a good choice for immobilizing older patients.

Reproduced with permission from Germa AB.

hips and knees, and they should never be used to treat hip fractures. Splinting devices such as vacuum mattresses that conform to body contours may be a good choice for immobilization in these cases (**FIGURE 37-11**). In hip and pelvic fractures, avoid log rolling the patient because you risk causing more damage and increased pain. When immobilization is indicated, patients with kyphosis will require padding. In general, padding should be done for comfort and to help decrease the likelihood of decubitus ulcer formation.

Additional treatment will depend on the patient's specific injuries, although there are a few general principles to keep in mind:

- Use caution inserting IV catheters and administering isotonic solutions. It is easy to overload an older person with sodium, and you must balance that risk with the need to maintain adequate perfusion pressure. Use small boluses, and reassess the patient frequently, especially for signs of pulmonary edema.
- Take steps to preserve temperature in geriatric trauma patients. Regulation of temperature is

slowed in older adults, and the blood in cold patients does not clot as well.

- Frail geriatric patients may not do well with a traction splint for a femoral fracture. If possible, place patients on a well-padded backboard and buttress them well with pillows secured firmly in place.
- Immobilize the cervical spine before transporting the patient. If a backboard is used, pad it generously because the skin of an older person may be damaged by the direct trauma of the pressure and the decrease in blood flow. Target areas where the bone is near the surface, from top to bottom: occiput, scapula, spinous processes, elbows, sacrum, and heels. A pressure ulcer can develop in as little as 45 minutes and can have devastating consequences.

Special Populations

Remember that older adults do not have the mechanisms that help keep them warm. Provide blankets and heat to prevent hypothermia.

Communication with older adults can be challenging in any situation, but it can become even more complicated when the patient is in pain, or is experiencing fear from trauma. Older people also tend to fear that a trauma may end their mobility and independence. Remember to provide psychological support, as well as medical treatment. Document assessment, treatment, and reassessment, including any changes in the patient's status.

Elder Abuse and Neglect

Reports of abuse, neglect, and other related problems among the nation's geriatric population are on the rise. **Elder abuse** is defined as any action or inaction on the part of an older person's family member, caregiver, or other associated person who takes advantage of the older adult's person (for example, physical abuse), property, or emotional state (**TABLE 37-6**). **Neglect** is the failure to provide needed care, services, or supervision.

The prevalence of elder abuse is not fully known for several reasons, including the following:

- Elder abuse is a problem that has been largely hidden from society.

TABLE 37-6 Categories of Elder Abuse

Category	Examples
Physical	• Assault • Neglect or abandonment • Dietary (malnutrition) • Poor maintenance of home • Poor personal hygiene • Sexual assault
Psychological	• Benign neglect • Verbal • Treating the person in a demeaning way • Deprivation of sensory stimulation
Financial	• Theft of valuables • Embezzlement

© Jones & Bartlett Learning.

- The definitions of abuse and neglect among older people vary.
- Victims of elder abuse are often hesitant to report the problem to law enforcement agencies or human and social welfare personnel.
- Elder abuse is most commonly seen as financial abuse, which may not be as visibly obvious.³⁵

An older adult who is being abused by a relative or caregiver may feel ashamed or guilty. The abused person may feel shame, anger, or guilt (or all three). If the abuser is a family member, the abused person may fear retribution or anger from other family members for reporting the abuse to an outside agency. If the abuser is not a family member, the abused older person may be afraid to report the abuse for fear of no longer receiving care.

The physical and emotional signs of abuse, such as rape, spouse beating, or nutritional deprivation, are often overlooked or inaccurately identified. Older women are particularly unlikely to report incidents of sexual assault to law enforcement agencies. Patients with sensory deficits, senility, and other forms of altered mental status, such as drug-induced depression, may not be able to report abuse.

The abused person is often frail with multiple chronic medical conditions; has dementia; and may have an impaired sleep cycle, sleepwalking, and periodically shout at others. The person may be incontinent and is generally dependent on others for ADLs.

Abusers of older people are sometimes products of child abuse, and the abuse that is inflicted on the person may be retaliatory. Most abusers are not trained in the particular care that the older person requires and have little relief time from the constant care demands of their own family. The stress associated with this situation may contribute to abusive behavior.

The abuser may also have marked fatigue, be unemployed and/or have financial difficulties, or be a substance abuser. With a careful eye, you can recognize the clues to these stressful situations and help guide the family toward programs in the community that are geared to helping the whole family. Programs such as adult day care, meals on wheels, or many local individualized programs help to decrease the stress put on the family, thus decreasing the chance of abuse.

Abuse is not restricted to the home; environments such as nursing homes, convalescent homes, and continuing care centers (assisted-living facilities) are also sites where older people sustain physical, psychological, financial, or pharmacologic abuse. Often, care providers in these environments consider older people to be management problems or categorize them as obstinate and undesirable patients.

Signs of Physical Abuse

Signs of abuse may be obvious or subtle. Inflicted bruises are usually found on the buttocks and lower back, genitals and inner thighs, cheeks or earlobes, neck, upper lip, and inside the mouth. Pressure bruises caused by the human hand may be identified by oval grab marks, pinch marks, or handprints. Human bites are typically inflicted on the upper extremities and can cause lacerations and infection. You should inspect the patient's ears for indications of twisting, pulling, or pinching or evidence of frequent trauma to the external ears. You should also investigate multiple bruises in various states of healing by questioning the patient and reviewing the patient's ADLs.

Burns are a common form of abuse. If you see burns, especially cigarette burns or physical marks that indicate that certain parts of the patient's body have been scalded systematically, you must suspect abuse. Typical abuse from burns are caused by contact with cigarettes, matches, heated metal, forced

immersion in hot liquids, chemicals, and electrical power sources.

It may be difficult to see a failure to thrive in an older patient who has been abused. You should observe the patient's weight and try to determine whether the patient appears undernourished or has been unable to gain weight in the current environment. Does the patient have a ravenous appetite? Has medication been withheld? Is money being withheld so the patient cannot buy food or medicine? You should also check for signs of neglect, such as evidence of a lack of hygiene, poor dental hygiene, poor temperature regulation, or lack of reasonable amenities in the home.

You must regard injuries to the genitals or rectum with no reported trauma as evidence of sexual abuse in any patient. Geriatric patients with an altered mental status may never be able to report sexual abuse. In addition, many women do not report cases of sexual abuse because of fear, shame, and a desire to forget the incident.

Assessment and Management of Elder Abuse

While you are assessing the patient, try to obtain an explanation of what happened. You should suspect abuse when answers to questions about what caused the injury are concealed or avoided.

You must also suspect abuse when you are given unbelievable answers. Be suspicious if you think, "Does this make sense?" or "Do I really believe this story?" while reviewing the patient's history. As an AEMT, you may be the first health care provider to observe the signs of possible abuse. Information that may be important in assessing possible abuse includes the following:

- Caregiver apathy about the patient's condition
- Overly defensive reaction by caregiver to your questions
- Caregiver does not allow patient to answer questions
- Repeated visits to the ED or clinic
- A history of being accident prone
- Soft-tissue injuries
- Unbelievable, vague, or inconsistent explanations of injuries
- Psychosomatic issues
- Chronic pain without medical explanation
- Self-destructive behavior

- Eating and sleep disorders
- Depression or a lack of energy
- A history of substance and/or sexual abuse

In addition to the life-saving care that you can provide the patient, your examination of the patient can help to reduce further trauma from abuse through its very identification. Repeated abuse can lead to a high risk of death.

If the patient is in stable condition but the situation is unsafe, see if the patient will accept transportation to the hospital. If the patient refuses transport, see if the person will accept help from the local **adult protective services (APS)**. In some cases, patients may be hesitant to go with EMS personnel

because of fear of caregiver retaliation. If the situation is immediately unsafe, notify law enforcement personnel and remain with the patient only if the scene remains safe to do so.

Consult local authorities, but in general, you should assume that you have the same obligation to report suspected elder abuse as you do suspected child abuse. Notify receiving hospital personnel of your concerns, report to the proper authorities based on local protocols, and factually document your findings. If you are in doubt, err on the side of caution and make a report. Note that it is not your responsibility to prove that the abuse occurred, only to report your findings according to protocols.

YOU are the Provider **SUMMARY**

1. What are some possible causes of confusion in geriatric patients?

Causes of confusion in geriatric patients include the common causes in patients of younger age, as well as delirium, dementia, and Alzheimer disease. Dementia develops slowly over a period of years rather than a few days. Alzheimer disease begins gradually with difficulty performing routine tasks and/or forgetting recent events. As it advances, personality changes, impaired judgment, and impaired ability to communicate thoughts or ideas become more prominent. Based on the information provided by the daughter, this patient is most likely experiencing a form of dementia.

2. Does this patient present with any risk factors that could affect his mortality?

Yes. Of the risk factors that affect mortality in older patients, this patient has the following: age older than 75 years, living alone, recent death of a spouse, and altered mental status. In older people who live alone, potential is increased for incorrect medication doses, which could result in inadvertent underdosing or overdosing.

3. Does this patient require immediate transport?

This patient requires immediate transport to the closest appropriate facility because he is presenting with signs and symptoms consistent with hypovolemic shock. This patient is confused, is slow to respond, has thready radial pulses, and his skin is cool, pale, and clammy. He warrants aggressive treatment for shock.

4. On the basis of the patient's presentation, what do you suspect is happening?

On the basis of clinical interpretation, the patient is experiencing GI bleeding that requires immediate treatment and transport. The patient stated he has been vomiting foul-smelling emesis; it can further be assumed that he is experiencing upper GI tract bleeding.

5. Does this patient require a second IV line?

This patient would potentially benefit from a second IV line because of profound hypotension and signs and symptoms of shock. A second IV access is valuable for fluid administration and to have a secondary access point should the first IV line become infiltrated or dislodged. Never delay transport to obtain a second IV line, however. It is more important to get the patient to definitive care rapidly.

6. What is the significance of the medications that the patient is taking?

This patient is taking Coumadin, Tenormin, and Glucophage. Coumadin is a blood thinner, which in the presence of GI bleeding can exacerbate the condition, resulting in increased bleeding and delayed clotting times. Tenormin is a beta-blocker that slows down the heart rate. The fact that this patient is taking Tenormin needs to be considered when interpreting the patient's heart rate. Normally, you would expect a patient in shock to present with tachycardia. In this case, however, Tenormin would cause the patient's heart rate to be lower; even in shock, the patient could have a normal blood pressure or even be bradycardic. Glucophage is an antidiabetic

YOU are the Provider SUMMARY *continued*

medication that should indicate that the patient has a history of diabetes. Because this patient was confused and taking Glucophage, it was wise to check his blood glucose level. Even though the shock explains the confusion, he could also be hypoglycemic based on his vomiting. With a careful evaluation of the patient's medications, you will be able to gain insight into the patient's present condition.

7. What are the potential hazards of the patient vomiting?

The biggest potential hazard of vomiting is aspiration. Treatment for this patient should include proper positioning and rapid transport.

8. Why should lactated Ringer solution be avoided in this patient?

Because of changes in the renal system of geriatric patients, they are susceptible to hyperkalemia. Although administering lactated Ringer solution to a younger patient may not appreciably increase potassium levels, the same amount of fluid may increase a geriatric patient's already elevated potassium level to become lethal.

Narrative

EMS dispatched to unknown medical problem. On arrival, find daughter who states her father "isn't acting normal." Patient is alert, slightly confused, and slow to answer questions. Patient states that he has been vomiting "foul" smelling emesis × 4 days and is weak and dizzy. Patient is cold to touch, 4-second capillary refill, and a thready, slow radial pulse. Checked pt's blood glucose level, which was normal (116 mg/dL). While assisting patient to a standing position to use the bathroom prior to transport, he becomes pale and radial pulse is absent when in standing position. Patient assisted back to supine position. 18-gauge IV line established to left AC with two normal saline boluses infusing. Initial vital signs as above. Patient placed on stretcher and secured in ambulance. Emergent transport initiated to Oschner Hospital. En route—second 250-mL bolus infusing due to persistent hypotension. Approximately 6 minutes from Oschner ED, patient vomits approximately 200 mL of coffee-ground-looking emesis. Suctioned airway and repositioned patient to left lateral position. On arrival at Oschner, care and report left with ED RN without incident.

End of report

Prep Kit

Ready for Review

- Treatment of older patients can present you with many challenges that are not encountered with younger patients that may be difficult.
- It is important to understand social and economic factors that can affect geriatric patients, including the economic impact of aging and independent and dependent living.
- AEMTs should be aware of advance directives such as DNR orders, as well as end-of-life care and considerations.
- Good communication techniques are important when working with older patients. Position yourself at the patient's level, look the patient in the eye, and remember to ask open-ended questions.
- The aging process is accompanied by changes in physiologic function. The decrease in the functional capacity of various organ systems can affect the way in which the patient responds to illness.
- A person's respiratory capacity undergoes substantial reductions with age because of decreases in the elasticity of the lungs and in the size and strength of the respiratory muscles, stiffening in the chest wall, and musculoskeletal changes.
- Within the cardiovascular system, changes include hypertrophy (enlargement) of the heart, arteriosclerosis (the stiffening of vessel walls), and deterioration of the electric conduction system of the heart.
- Changes in the nervous system result in a decrease in sensory function, as evidenced by visual changes (glaucoma and cataracts are common) and hearing loss.
- Changes in the endocrine system may result in diabetes and thyroid abnormalities in older patients.
- The GI system changes as appetite decreases, digestion becomes more difficult as a result of a reduction in saliva, and dental loss contributes to digestive problems. Slow movement through the digestive system and use of narcotic pain medications may result in constipation.
- Geriatric patients may experience renal system changes. Although an older patient's kidneys may function well on a daily basis, they can be easily overwhelmed by additional stresses such as illness. Therefore, acute illness in older adults is often accompanied by derangements in fluid and electrolyte balance.
- Aging is associated with a widespread decrease in bone mass in men and women, but especially among postmenopausal women. Bones become more brittle and tend to break more easily.
- Within the integumentary system, the skin wrinkles and thins, elastin and collagen decrease, and the sebaceous glands produce less oil, making the skin drier. In addition, the skin does not replace itself as quickly. This combination places older adults at higher risk for skin injury and complications.
- The ability of a geriatric person to regulate temperature is decreased, resulting in increased cases of heat and cold illness.
- The health problems of older people are quantitatively and qualitatively different from those of younger people. The special problems of older people require special approaches.
- Heart disease is the leading cause of death among older adults in the United States, along with cancer, stroke, COPD, pneumonia, diabetes, and trauma.
- Abdominal problems are common in older patients and extremely difficult to assess. AAA and GI bleeding are serious emergencies and require rapid transport.
- In older adults, delirium often replaces or confounds the typical presentation caused by a medical problem, an adverse medication effect, or drug withdrawal.
- Unlike delirium, dementia is a disease that produces irreversible brain failure. Alzheimer disease is a neurologic cause of dementia.
- Older patients with diabetes whose blood glucose levels tend to be high are susceptible to hyperosmolar hyperglycemic nonketotic

syndrome (HHNS). The most frequent cause for HHNS is infection. Presentation is likely to be acute confusion with dehydration.

- The GEMS diamond is a valuable assessment tool to help providers recall key considerations for geriatric patients.
- Although assessment of the older patient involves the same basic approach as with any other patient, you may have to take a slower approach to the older patient. To perform an adequate assessment will require patience, but it is time well spent.
- The injury or medical condition may be worse than indicated by the existing signs and symptoms, and the injuries and conditions that are found will have a more profound effect than they would in a younger patient.
- In addition to the critical needs that an underlying medical problem may cause, the older patient's condition is more unstable than a younger patient's and has an increased possibility for sudden, rapid deterioration.
- When a patient's chief complaint seems trivial, it may be necessary to go through a review of systems to confirm that you are not missing important pieces of information. Follow up with further questions when you determine more information is necessary.
- You must obtain an accurate history of the patient, be compassionate, and communicate your findings effectively. Be an advocate for your patients.
- The secondary assessment of older patients can be difficult. Poor cooperation and easy fatigability may require that you keep manipulations of the patient to a minimum. You may have to remove many layers of clothing from an older adult patient to perform an adequate exam.
- The AEMT must try to obtain an accurate list of medications and dosages, because many geriatric patients take multiple medications and are particularly susceptible to adverse drug reactions.
- Several factors place an older person at higher risk of trauma than a younger person: slower reflexes, visual and hearing deficits, equilibrium disorders, and an overall reduction in agility.
- Most geriatric trauma cases involve falls or motor vehicle crashes. Falls are evenly divided between those resulting from extrinsic (external) causes, such as tripping on a loose rug or slipping on ice, and those resulting from intrinsic (internal) causes, such as a dizzy spell or a syncopal attack.
- The prevalence of elder abuse is not fully known because many patients do not report it. Abusers are often family members who must care for the older person in addition to caring for their own spouses and children.
- Elder abuse also occurs in nursing, convalescent, and continuing care centers. Elder abuse can be gruesome, vulgar, and barbaric; however, your responsibility is to provide potentially life-saving care to the patient and try to reduce additional abuse through identification of the problem.
- The duty that we owe to our older population should be no less than we would expect in our own golden years.

Vital Vocabulary

abdominal aortic aneurysm (AAA) A condition in which the walls of the aorta in the abdomen weaken and blood leaks into the layers of the vessel, causing it to bulge.

activities of daily living (ADLs) The basic activities a person usually accomplishes during a normal day, such as eating, dressing, and washing.

adult protective services (APS) An organization that investigates cases involving abuse and

neglect and provides case management services in some cases.

aneurysm A swelling or enlargement of a part of an artery, resulting from weakening of the arterial wall.

arteriosclerosis The thickening of the arterial walls that results in a loss of elasticity and concomitant reduction in blood flow.

atherosclerosis A disorder in which cholesterol and possibly calcium build up inside the walls of blood vessels, forming plaque, which eventually

leads to partial or complete blockage of blood flow; a plaque can become a site where blood clots can form, detach, and travel elsewhere in the circulatory system (embolize); the most common form of arteriosclerosis.

cataract Clouding of the lens of the eye or its surrounding transparent membrane.

decubitus ulcers Ulcers that occur when pressure is applied to body tissue, resulting in a lack of perfusion and ultimately necrosis.

delirium An acute change in mental status marked by the inability to focus, think logically, and maintain attention.

dementia The slow onset of progressive disorientation, shortened attention span, and loss of cognitive function.

dependent living A type of care in which a person receives assistance based on the person's needs or restrictions; can range from the least restrictive retirement community to the structured skilled nursing facility and dementia/Alzheimer disease specialty care facilities. Sometimes known as residential.

elder abuse Any action or inaction on the part of a family member, caregiver, or other associated person that takes advantage of the older adult's person, property, or emotional state; also called parent battering.

geriatrics The assessment and treatment of disease in someone 65 years or older.

glaucoma A disease of the eye caused by an increase in intraocular pressure; when severe enough, this may damage the optic nerve and potentially cause permanent loss of vision.

hematemesis Vomit with blood; can either look like coffee grounds, indicating the presence of partially digested blood, or contain bright-red blood, indicating active bleeding.

homeostasis A tendency to constancy or stability in the body's internal environment; the balance of all systems of the body.

hospice An organization that provides end-of-life care to patients with terminal illnesses and their families.

hyperosmolar hyperglycemic nonketotic syndrome (HHNS) A metabolic derangement that occurs principally in patients with type 2 diabetes; it is characterized by hyperglycemia, hyperosmolarity, and an absence of significant ketosis.

kyphosis A condition in which the back becomes hunched over due to an abnormal curvature of the spine.

macular degeneration Deterioration of the central portion of the retina.

melen Black, tarry, foul-smelling stools caused by digested blood that has traveled through the digestive tract; caused by upper gastrointestinal bleeding.

methicillin-resistant *Staphylococcus aureus* (MRSA) A bacterium that can cause infections in different parts of the body and is often resistant to commonly used antibiotics; it is transmitted by different routes, including the respiratory route, and can be found on the skin, in surgical wounds, and in the bloodstream, lungs, and urinary tract.

neglect Refusal or failure on the part of the caregiver to provide life necessities, such as needed care, services, or supervision.

neuropathy A group of conditions in which the nerves leaving the spinal cord are damaged, resulting in distortion of signals to or from the brain.

osteoporosis A generalized bone disease, commonly associated with postmenopausal women but occurring in either sex, in which there is a reduction in the amount of bone mass, resulting in increased susceptibility to fractures after minimal trauma.

polypharmacy The simultaneous use of many medications by the same patient.

presbycusis An age-related condition of the ear that produces progressive bilateral hearing loss that is most noted at higher frequencies.

proprioception The ability to perceive the position and movement of one's body or limbs.

pulmonary embolism A blood clot that breaks off from a large vein and travels to the blood vessels of the lung, causing obstruction of blood flow.

respiratory syncytial virus (RSV) A virus that causes an infection of the lungs and breathing passages; can result in other serious illnesses that affect the lungs or heart, such as bronchiolitis and pneumonia; highly contagious and spread through droplets.

sacral edema Swelling that presents around the sacral region of the spinal column.

syncope The temporary loss of consciousness and postural tone caused by diminished cerebral blood flow.

vasoconstriction Narrowing of the diameter of a blood vessel.

vasodilation Widening of a blood vessel.

Chapter 38

Patients With Special Challenges

NATIONAL EMS EDUCATION STANDARD COMPETENCIES

Special Patient Populations

Applies a fundamental knowledge of growth, development, aging, and assessment findings to provide basic and selected advanced emergency care and transportation for a patient with special needs.

Patients With Special Challenges

Recognizing and reporting abuse and neglect (Chapter 36, *Pediatric Emergencies*, and Chapter 37, *Geriatric Emergencies*)

Healthcare implications of

- Abuse (Chapter 36, *Pediatric Emergencies*, and Chapter 37, *Geriatric Emergencies*)
- Neglect (Chapter 36, *Pediatric Emergencies*, and Chapter 37, *Geriatric Emergencies*)
- Homelessness (p 1874)
- Poverty (p 1874)
- Bariatrics (p 1860)
- Technology dependent (pp 1862–1872)
- Hospice/terminally ill (pp 1873–1874)
- Tracheostomy care/dysfunction (pp 1862–1864)
- Home care (pp 1872–1873)
- Sensory deficit/loss (pp 1853–1856)
- Developmental disability (pp 1849–1853)

KNOWLEDGE OBJECTIVES

1. List examples of patients with special needs whom advanced emergency medical technicians (AEMTs) may encounter during an emergency. (pp 1848–1849)
2. Describe how to interact with patients with special needs, based on the nature of their impairment. (pp 1849, 1851–1852)

Trauma

Applies fundamental knowledge to provide basic and selected advanced emergency care and transportation based on assessment findings for an acutely injured patient.

Special Considerations in Trauma

Recognition and management of trauma in

- Pregnant patient (Chapter 35, *Obstetrics and Neonatal Care*)
- Pediatric patient (Chapter 36, *Pediatric Emergencies*)
- Geriatric patient (Chapter 37, *Geriatric Emergencies*)

Pathophysiology, assessment, and management of trauma in the

- Pregnant patient (Chapter 35, *Obstetrics and Neonatal Care*)
- Pediatric patient (Chapter 36, *Pediatric Emergencies*)
- Geriatric patient (Chapter 37, *Geriatric Emergencies*)
- Cognitively impaired patient (pp 1852–1853)

3. Discuss the special patient care considerations that may be required when providing emergency medical care to patients with developmental disabilities, including patients with autism spectrum disorder, Down syndrome, and prior brain injuries. (pp 1849–1853)
4. Describe different types of visual impairments and the special patient care considerations that may be required when providing emergency medical care for these patients depending on the level of their disability. (pp 1853–1854)
5. Describe different types of hearing impairments and the special patient care considerations that may be required when providing emergency medical care for these patients, including tips for effective communication. (pp 1854–1855)
6. Describe the four types of hearing aids that may be worn by patients, including troubleshooting strategies that may help to fix a hearing aid that is not working. (pp 1855–1856)
7. Discuss the special patient care considerations that may be required when providing emergency medical care to patients who have the following conditions:
 - Cerebral palsy (pp 1856–1857)
 - Cystic fibrosis (p 1857)
 - Multiple sclerosis (pp 1857–1858)
 - Muscular dystrophy (p 1858)
 - Spina bifida (pp 1858–1859)
 - Paralysis (pp 1859–1860)
8. Define obesity and bariatrics. (p 1860)
9. Discuss the special patient care considerations that may be required when providing emergency medical care to bariatric patients, including the best way to move a patient with obesity. (pp 1860–1862)
10. Discuss the special patient care considerations that may be required when providing emergency medical care to patients who rely on a form of medical technology assistance, including the following:
 - Tracheostomy tube (pp 1862–1864)
 - Mechanical ventilator (pp 1866–1867)
 - Apnea monitor (p 1867)
 - Internal cardiac pacemaker (pp 1867–1868)
 - Left ventricular assist device (p 1868)
 - External defibrillator vest (pp 1868–1869)
 - Intra-aortic balloon pump (p 1869)
 - Central venous catheter (pp 1869–1870)
 - Gastrostomy tube (p 1870)
 - Shunt (pp 1870–1871)
 - Vagus nerve stimulator (p 1871)
 - Colostomy, ileostomy, or urostomy bag (pp 1871–1872)
11. Describe the assessment and management process for patients with special needs. (p 1872)
12. Describe home care, the types of patients it serves, and the services it encompasses. (pp 1872–1873)
13. Discuss hospice and palliative care. (pp 1873–1874)
14. Explain the responsibilities of AEMTs when responding to calls for terminally ill patients who have do not resuscitate orders. (pp 1873–1874)
15. Discuss the issues of poverty and homelessness in the United States, including the negative effects on a person's health, and the role of AEMTs as patient advocates. (p 1874)

SKILLS OBJECTIVES

1. Demonstrate different strategies to communicate effectively with a patient who is hard of hearing or deaf. (p 1854)
2. Explain how to suction and clean a tracheostomy. (pp 1864–1865, Skill Drill 38-1)

Introduction

Many children and adults live with chronic diseases and injuries. Thanks to advances in medicine and medical technology, many people with these diseases and injuries live at home or in other environments outside the hospital setting. As an advanced

emergency medical technician (AEMT), you should be familiar with the special needs created by chronic diseases and injuries.

Some examples of patients with special needs include the following:

- Children who were born prematurely and who have associated respiratory conditions

- Infants or small children with congenital heart disease
- Patients with neurologic disease (occasionally caused by hypoxemia at the time of birth, as with cerebral palsy)
- Patients with congenital or acquired diseases resulting in altered body function that requires medical assistance for breathing, eating, urination, or bowel function
- Patients with sensory deficits such as hearing or visual impairments
- Geriatric patients with chronic diseases requiring visitation from a home health care service

You may be called on to treat children and adults who are living at home who depend on mechanical ventilators, intravenous (IV) pumps, or other devices to maintain their lives. You should assess and care for patients with special needs the same way you care for your other patients, although you may adapt your approach to communication depending on the patient's special needs. Your priority is to manage airway, breathing, and circulation (ABCs). Incorporate the patient, family members, and/or caregivers into your process, and solve problems as a group. Remember your ultimate goal: to give the patient the best emergency medical care possible, in the most efficient way, and still accommodate for the patient's individual needs.

Developmental Disability

A **developmental disability** refers to insufficient development of the brain, resulting in some level of dysfunction or impairment. Developmental disabilities can include intellectual, hearing, or vision impairment. As the term implies, the disability appears during a person's development—that is, during infancy, childhood, or adolescence.

Intellectual disability results in the inability to learn and socially adapt at a normal developmental rate. An intellectual disability may be caused by genetic factors, congenital infections, complications at birth, malnutrition, or environmental factors. Prenatal drug or alcohol use may also cause intellectual disability, such as fetal alcohol syndrome. Other causes that may occur after birth include traumatic brain injury and poisoning (eg, from lead or other toxins).

A person with a slight intellectual impairment may appear slow to understand or have a limited

vocabulary and might behave immaturely in comparison with their peers. People with severe intellectual disabilities may not have the ability to care for themselves, communicate, understand, or respond to their surroundings.

Speaking to patients and family members will give you a good idea of how well the patient can understand you and how the patient will interact with you. Family or friends of the patient may also be able to supply additional medical information regarding the patient.

Some patients with disabilities may have difficulty adjusting to change or a break in routine, so an emergency call that generates a roomful of strangers can be overwhelming. An anxious patient may have difficulty interacting with you. Make every effort to respect the patient's wishes and concerns; take as much time as necessary to calmly and clearly explain the treatment the patient is about to receive.

Autism Spectrum Disorder

Autism and **autism spectrum disorder (ASD)** are general terms used to describe a complex disorder that varies greatly in signs and symptoms. Autism is a pervasive developmental disorder characterized by impairment of social interaction. Other characteristics can include severe behavioral problems, repetitive motor activities, and verbal and nonverbal language impairment. The spectrum of disability is wide. Some children with autism will grow up to be independent, whereas others will be unable to care for themselves.

Patients with autism do not use or understand nonverbal means of communication, such as gestures. They frequently have difficulty making eye-to-eye contact and resist encouragement to do so. They have extreme difficulty with complex tasks that require many steps and do best with simple, one-step directions, such as "Please put on your shoes." Some patients with autism tend to become confused during long conversations and have trouble answering open-ended questions (for example, "What sorts of things do you enjoy doing?"). They might talk in robotic or monotone speech patterns and sometimes repeat phrases over and over again. Many patients with autism confuse pronouns and will say "you" when they mean "I," as in, "You are going to the hospital," when they mean, "I am going to the hospital." A small percentage of patients with

autism do not speak at all, but instead rely on actions such as pulling parents and caregivers around by the hand to get their needs met.

Street Smarts

Patients with autism often have abnormal sensory responses and may not feel cold, heat, or pain as others do. They may respond to pain by laughing, humming, singing, or removing clothing. Applying bandages or tape to these patients may also cause anxiety or aggression. For noncritical patients, use a toe-to-head approach for assessment to lessen anxiety. Explain what you are doing as you progress. Even nonverbal patients often understand speech.

Patients with autism may have increased sensitivity to noise or physical stimulation. Keep the transport environment calm and minimize stimulation to help lessen anxiety. Limit the use of lights and siren when not absolutely necessary. Ear plugs or headphones may also be beneficial. Patients may have a short phrase, item, or particular routine they use that provides comfort. Allowing their normal routine to be carried out when practical may avoid triggering outbursts or escalating behavior.

Street Smarts

You may need to use distraction techniques while assessing the patient. Allowing the patient to listen to your heart with the stethoscope first may alleviate the fear associated with an unfamiliar device.

No simple explanation exists as to why autism develops in children. According to the US Centers for Disease Control and Prevention (CDC), approximately 1 in every 54 American children is diagnosed with autism. The prevalence in boys is five times the prevalence in girls.¹ Autism is typically diagnosed by age 3 years. The parents or caregivers often report unique, repetitive behaviors (hand flapping, twirling objects) or isolated abnormal behaviors. Many children with autism receive special instruction and care in school-based settings, but this was not always the case in the past. It is likely that some older adults with autism have never been diagnosed and, therefore, have never received any assistance.

Patients with autism generally have medical needs similar to those of their peers without autism. If permitted by departmental policy, allow a caregiver or family member to ride in the patient compartment. Rely on parents or caregivers for information, and involve them in the treatment of the patient. As with any patient, explain what you are going to do before you do it. Move slowly, stay calm, and show the patient what to expect by demonstrating the exam on a parent or caregiver first. Use short, direct, and simple phrases when communicating, and allow extra time for the patient to process the communication.

Down Syndrome

Down syndrome is characterized by a genetic chromosomal defect that can occur during fetal development, resulting in mild to severe intellectual impairment (**FIGURE 38-1**). The normal human somatic cell contains 23 pairs of chromosomes. In most cases, Down syndrome, also known as trisomy 21, occurs when the two 21st chromosomes fail to separate, so that the ovum or sperm contains 24 chromosomes. When an ovum or sperm with an extra chromosome 21 combines with a normal cell from the other parent, an embryo with 3 copies of chromosome 21 is formed. The extra copy of chromosome 21 disrupts the normal course of development.

According to the CDC, approximately 6,000 babies are born with Down syndrome in the United States each year. Increased maternal age (older than

FIGURE 38-1 A child with Down syndrome.

© PhotoCreate/Shutterstock.

35 years) and a family history of Down syndrome are known risk factors for this condition. A variety of physical abnormalities are associated with Down syndrome: a round head with a flat occiput; an enlarged, protruding tongue; slanted, wide-set eyes; folded skin on either side of the nose, covering the inner corners of the eye; short, wide hands; a small face and features; congenital heart defects; thyroid problems; and hearing and vision problems.² People with Down syndrome usually do not have all of these signs, but a diagnosis can be made rapidly at birth because a combination of signs can be seen. Depending on their level of intellectual disability, people with Down syndrome may lead relatively independent lives. They may be employed, vote, and get involved in their communities.

People with Down syndrome are at increased risk for medical complications, including those that affect the cardiovascular, sensory, endocrine, musculoskeletal, dental, gastrointestinal, and hematologic systems, as well as neurologic development.³ People with Down syndrome may also have instability of the cervical spine. This can be a cause of injury in children when they participate in contact sports without having undergone proper screening.

Emergency treatment for patients with Down syndrome should include airway management, supplemental oxygen, and IV access. In patients with heart failure, administer diuretics with judicious fluid resuscitation only if necessary.

Because people with Down syndrome often have large tongues and small oral and nasal cavities, bag-mask ventilation can be challenging. Misalignment of the teeth and other dental anomalies may be present. The enlarged tongue and dental

anomalies can lead to speech abnormalities as well. In the case of airway obstruction, a jaw-thrust maneuver may be all that is needed to clear the airway. In an unresponsive patient, the jaw-thrust maneuver or a nasopharyngeal (nasal) airway may be necessary. Call for paramedic backup early if you suspect the need for advanced airway management.

In some people with Down syndrome, the atlantoaxial joint, where the first two cervical vertebrae meet, is unstable. This condition is termed atlantoaxial instability (AAI). Most patients with AAI do not show symptoms; however, they are at increased risk of complications when they experience trauma. Keep this in mind when you receive a call for a musculoskeletal problem or possible neurologic problem in a patient with Down syndrome. If the atlantoaxial joint becomes dislocated, as may occur with trauma, the patient may experience difficulty walking, neck pain or decreased neck mobility, and sensory deficits. Such a dislocation can even cause spinal cord injury. AAI is diagnosed with a radiograph of the cervical vertebrae.

Compared to the general population, epilepsy is more common among people with Down syndrome. Most of the seizures are tonic-clonic. Patient management is the same as with other patients with seizures. Chapter 19, *Neurologic Emergencies*, discusses the emergency management of seizures in detail.

Patient Interaction

It is normal to feel somewhat uncomfortable when initiating contact with a patient with a disability, especially if you have not encountered such situations

YOU are the Provider

Part 1

Your ambulance is dispatched to a local group home for a man having a seizure. Based on previous responses to this location, you are aware that the residents all have some type of disability and often require complex management. As you arrive on scene, you are directed to the dining area where you find Gary. You know from previous encounters that he has Down syndrome and often experiences seizures. Presently the patient is not having a seizure and appears to be breathing adequately, but he remains in a postictal state. The on-duty caregiver states that Gary had a tonic-clonic seizure, lasting approximately 90 seconds, and it resolved on its own.

1. What abnormalities are associated with Down syndrome?
2. What type of medical complications may patients with Down syndrome experience?

frequently. The best plan of action is to treat the patient as you would any other patient.

Approach the patient in a calm and friendly manner, watching for signs of increased anxiety or fear. Remember, you are a stranger and are approaching with a group of people. The patient may not understand your uniform or realize that you and your team are there to help. It may be helpful to have your team members wait until you can establish a rapport with the patient. You can then introduce the team members, explain what they are going to do, and slowly bring them forward.

Begin interacting with the patient by introducing yourself, shaking the patient's hand if the patient will allow it. Converse with the patient as you normally would. For example, say, "Your mother called us. She says you're not feeling well today, and we're here to help you feel better. My friend John is going to take your blood pressure." Allow the patient to see and touch your equipment before you use it. Move slowly but deliberately, explaining beforehand what you are going to do, just like you would with any other patient.

Watch carefully for signs of fear or reluctance from the patient. Do your best to soothe the patient's anxiety and/or discomfort as you work through your assessment and treatment plan. Make

sure you are at eye level with the patient. If the patient is sitting, then kneel or sit down. By initially establishing trust and communication, you will have much better luck successfully executing your treatment plan.

Brain Injury

A patient with a prior brain injury may be difficult to assess and treat. Patients with brain injuries may face a complex array of challenges related to the injury. In such cases, obtaining a complete medical history from the patient, family, and friends will be helpful. You will need to tailor your interaction with patients with brain injuries to their specific abilities. Take the time to speak with the patient and family to establish what is considered normal for the patient; for example, determine whether the patient has cognitive, sensory, communication, motor, behavioral, or psychological deficits. Chapter 30, *Head and Spine Injuries*, discusses head injuries and traumatic brain injuries in detail.

When you care for a patient with a prior brain injury, talk in a calm, soothing tone, and watch the patient closely for signs of anxiety or aggression. In some cases, the patient may need to be specifically positioned or restrained to ensure your safety and the safety of the patient. Although not all people

YOU are the Provider

Part 2

You ask the caregiver about the patient's medical history, and she states he has a developmental disability. Even though Gary is 37 years old, he has the mental capacity of a 6-year-old. The caregiver also states he has a central venous catheter and a gastrostomy tube. You approach the patient and find that he has a patent airway and is breathing adequately. However, owing to the postictal state, you instruct your partner to administer oxygen with a nonrebreathing mask. You attempt to communicate with the patient, but he remains nonverbal. You ask the caregiver whether this is normal for him, and she states "No, he can usually answer simple questions."

Recording Time: 1 Minute

Appearance	Fair
Level of consciousness	Decreased
Airway	Patent
Breathing	12 breaths/min
Circulation	Warm and dry

- How should you interact with a patient with Down syndrome?
- How should you incorporate the caregiver into your treatment?

with brain injuries have physical impairments, do not expect the patient to walk to the ambulance or stretcher. As always, treat the patient with respect, use the patient's name, explain procedures, and reassure the patient throughout the process.

Sensory Disabilities

Visual Impairment

Visual impairments may result from a multitude of causes—a congenital defect, disease, injury, infection (eg, the cytomegalovirus), or degeneration of the eyeball, optic nerve, or nerve pathway (eg, with aging). The degree of visual impairment may range from partial to total. Some patients have a loss of peripheral or central vision; others can distinguish light from dark or discern general shapes.

Visual impairments may be difficult to recognize. During your scene size-up, look for signs that indicate the person is visually impaired, such as the presence of eyeglasses, a cane, or a service animal (**FIGURE 38-2**). Immediately introduce yourself

when you enter the room. Have your team members introduce themselves so the patient can identify their voices and locations. In addition, retrieve any visual aids (eg, eyeglasses) and give them to your patient to make the interaction more comfortable for the patient.

A visually impaired person may feel vulnerable, especially during the chaos of an incident scene. This person may have learned to use other senses such as hearing, touch, and smell to compensate for the loss of sight, and the sounds and smells of the scene may be disorienting. Remember to tell the patient what is happening, identify noises, and describe the situation and surroundings, especially if you must move the patient.

Words of Wisdom

Service animals are not classified as pets and should, by law, be allowed to stay with a visually impaired patient unless it is a critical situation or the animal is out of control. Review the Service Animals section in the Americans with Disabilities Act for further information.

FIGURE 38-2 A service dog is easily identified by its special harness.

© Juice Images/Getty Images.

Some patients use a cane or walker. Even if the person will be carried out on your gurney, do not forget to take the patient's cane or walker. Unless it is a critical situation, the service animal can remain with the patient and will provide reassurance for the patient and prevent delays in transport; however, in some cases, you may need to make arrangements for the care or accompaniment of the animal. A friend or animal control officer can be helpful in this situation.

An ambulatory patient may be led by a light touch on the arm or elbow. You may also allow the patient to rest a hand on your shoulder, as this may enhance the patient's sense of balance and security while moving. Consider asking patients which method they prefer to use while traveling to the

Words of Wisdom

Allow a visually impaired patient to stay in contact with you by keeping one hand on the patient or allowing the patient to hold onto you.

ambulance. Patients should be gently guided but never pulled or pushed. Communicate about obstacles in advance. Statements such as, “You’re approaching the stairs. We’re going to take five steps down,” will allow the patient to anticipate and navigate the obstacles safely.

Hearing Impairment

Hearing impairment may range from a slight hearing loss to total deafness. Some patients may have difficulty with pitch, volume, and speaking distinctly. Some patients learn to speak even though they have never heard sounds. Others may have heard speech and learned to talk but have since sustained partial or total hearing loss, leading them to speak too loudly. Parkinson disease and other disease processes may cause the patient to slur words, speak very slowly, or speak in a monotone.

The two most common forms of hearing loss are known as sensorineural deafness and conductive hearing loss. **Sensorineural deafness**, or nerve damage, is the most common hearing loss you will encounter in the field. Sensorineural deafness may be caused by a lesion or damage of the inner ear. Older adults will have some degree of sensorineural hearing loss because of advanced age. **Conductive hearing loss** is caused by a faulty transmission of sound waves, which can occur from a variety of causes, including an accumulation of wax within the ear canal, fluid in the middle ear from infection or allergies, a benign tumor, or a perforated eardrum.

During your scene size-up, look for clues that a person could be hard of hearing or deaf, including

the presence of hearing aids, poor pronunciation of words, and failure to respond to your presence or questions. Check to make sure the hearing aid is in place. Most people who are hard of hearing have learned to read body language, such as hand gestures and lip movement. Therefore, face the patient while communicating so the patient can see your mouth; do not exaggerate your lip movements or look away. Position yourself approximately 18 inches (46 cm) directly in front of the patient. Because patients who are hard of hearing typically have more difficulty hearing higher-frequency sounds, never shout if the patient seems to have difficulty hearing you; instead, try lowering the pitch of your voice.

Ask the patient, “How would you like to communicate with me?” American Sign Language may be the patient’s preferred method of communication (**FIGURE 38-3**). An interpreter, family member, or friend may be able to interpret. If an interpreter is not readily available, then call your receiving facility early on to request one. Ideally, an interpreter will arrive before you begin your assessment. Other patients may prefer written communication or communication of concepts or procedures with gestures or pictures.

Here are some helpful tips for working with patients who are hard of hearing or deaf:

- If indoors, then adjust the lighting so the patient can see you.
- Face the patient and speak slowly and distinctly. The patient may want to read your lips.
- Change speakers. Given that 80% of hearing loss is related to an inability to hear high-pitched

A

B

C

FIGURE 38-3 Consider learning common terms in American Sign Language related to illness and injury. **A.** Sick. **B.** Hurt. **C.** Help.

sounds, look for a team member with a low-pitched voice.

- Provide paper and a pencil so you may write your questions and the patient may write responses.
- Have only one person ask interview questions, to avoid confusing the patient.
- Try the “reverse stethoscope” technique: put the earpieces of your stethoscope in the patient’s ear and speak softly into the diaphragm of the stethoscope to amplify your voice.

Street Smarts

Some patients who are hard of hearing are sensitive to loud noises close to their ears. Remember to use a normal tone of voice when speaking to these patients.

Words of Wisdom

When you care for a patient who is hard of hearing, one communication solution is to place the ear pieces of your stethoscope into the patient’s ears while you speak softly into the diaphragm of the stethoscope.

Hearing Aids

A hearing aid is essentially a device that makes sound louder. Hearing aids cannot restore damaged hearing to normal, but they do improve hearing and listening ability. Four types of hearing aids are available (**FIGURE 38-4**):

- **Behind-the-ear.** The working parts are contained in a plastic case that rests behind the ear.

A

B

C

D

E

FIGURE 38-4 Different types of hearing aids. **A.** Behind-the-ear. **B.** Conventional body. **C.** In-the-canal. **D.** In-the-ear. **E.** Completely in-the-canal.

A: © Piotr Marcinski/Shutterstock; B: © Stine Lise Nielsen/Shutterstock; C: © Steve Hamblin/Alamy Stock Photo; D: © Terry Smith Images/Alamy Stock Photo; E: © Jiri Hera/Shutterstock.

- **Conventional body.** This older style is generally used by people with profound hearing loss. This type fits within the ear.
- **In-the-canal and completely in-the-canal.** These hearing aids are contained in a tiny case that fits partly or completely into the ear canal.
- **In-the-ear.** All parts are contained in a shell that fits in the outer part of the ear.

Implantable hearing aids are also an option for patients with less profound hearing loss. It is preferable to have the patient insert their own hearing aid. Provide assistance if needed. To insert a hearing aid, follow the natural shape of the ear. The device needs to fit snugly without forcing. If you hear a whistling sound after the device is inserted and turned on, then the hearing aid may not be in far enough to create a seal, or the volume may be too loud. Try repositioning the hearing aid, or remove it and turn down the volume. If you cannot insert the hearing aid after two tries, then put it in its box, take it with you, and document the transport and transfer of hearing aids to hospital personnel. Never try to clean hearing aids, and do not get them wet.

If a patient's hearing aid is inserted correctly but is still not working, then try troubleshooting the problem. First, make sure the hearing aid is turned on. Next, try a fresh battery, and check the tubing to make sure it is not twisted or bent. Check the switch to make sure it is set on M (microphone), not T (telephone). For a conventional body-type hearing aid, try a spare cord; the old one may be broken or shorted. Finally, check the ear mold to make sure it is not clogged with earwax.

Physical Disabilities

Cerebral Palsy

Cerebral palsy is a term for a group of disorders characterized by poorly controlled body movement (**FIGURE 38-5**). This disorder results from developmental brain defects in utero; traumatic brain injury at birth or in early childhood; oxygen deprivation at birth; or from infection, such as meningitis, during the neonatal period or infancy. There may also be a genetic cause. Patients with cerebral palsy can have symptoms that range from mild to severe, involving spastic movements of their limbs and inability to maintain proper posture.

Cerebral palsy is also associated with other conditions such as visual and hearing impairments,

FIGURE 38-5 A person with cerebral palsy.

© Sally and Richard Greenhill/Alamy Stock Photo.

difficulty communicating, epilepsy (seizures), and intellectual disabilities.

Some people with cerebral palsy are able to learn to walk with assistive devices, whereas others need support even to sit and cannot stand, walk, or speak. If the person is able to speak, then grimacing and uncontrolled movement may make speaking difficult and the person's speech hard to understand. To cope with ordinary tasks, many people with cerebral palsy use computerized household controls and speaking aids. Motorized wheelchairs may be controlled with a joystick or mouth control. Specially shaped chairs and pillows may be custom built to facilitate the person's comfort and ease movement. Toys may also be adapted to allow for learning and play. In addition, computers may be specially configured to aid the person with speech simulation and provide the ability to perform household tasks, such as temperature control and lighting.

As with all patients, assessing the ABCDEs (airway, breathing, circulation, disability, and exposure) is of the utmost importance. Closely observe the airway status of a patient with cerebral palsy because the patient may have increased production of secretions and **dysphagia**, or difficult swallowing, requiring aggressive suctioning to clear the airway.

When you care for a patient with cerebral palsy, note the following:

- Do not assume that all patients with cerebral palsy have an intellectual disability. Although 50% have some intellectual disability, many people with cerebral palsy have a normal

intelligence quotient or only slight intellectual impairment.⁴

- Limbs are often underdeveloped and are susceptible to injury (eg, a fall from a wheelchair).
- Patients who have the ability to walk may have an unsteady gait and are susceptible to falls.
- If the patient has a specially made pillow or chair (as many pediatric patients do), the patient may prefer to use it during transport. Remember to pad the patient to ensure comfort, and never force a patient's extremities into any position.
- Whenever possible, transport walkers or wheelchairs with the patient.
- About 25% to 35% of children with cerebral palsy have epilepsy, according to the Epilepsy Foundation.⁵ Be prepared to treat the patient during a seizure if one occurs, and keep a suctioning unit available.

Cystic Fibrosis

Infants and young children may be diagnosed with **cystic fibrosis (CF)** (mucoviscidosis), a genetic disorder that is characterized by increased production of mucus in the lungs and digestive system. CF is caused by a defective recessive gene, inherited from each parent, which disrupts the normal function of cells that make up the sweat glands in the skin and that also line the lungs and the digestive and reproductive systems. The end result is that the mucus becomes thick, sticky, and hard to move. The mucus holds germs, causing the lungs to become infected. The increased mucus impairs respiration, disrupts digestion of food, predisposes the patient to repeated lung infections, and may become a life-threatening emergency in severe situations.

Patients with CF are susceptible to the development of venous thrombosis. Pulmonary manifestations include pneumonia, pneumothorax, cough, respiratory distress, and respiratory failure. Malnutrition and a poor growth rate are not uncommon symptoms; in some cases, a child with CF may fail to thrive. Mild cases can go undetected until after a patient reaches adulthood. CF often causes death in childhood because of chronic pneumonia secondary to the very thick pathologic mucus in the airway. Because of advances in treatment, the life expectancy for CF patients improves each year. Children born today with CF have an average life expectancy in their late 40s.

Patients with CF receive frequent or continuous treatment with antibiotics. Medical devices promoting lung function and removal of mucus may also be used by patients with CF. Patients may be on intermittent or continuous home oxygen, and a significant number of patients with CF await or receive lung transplants to prolong and improve the quality of life. You may encounter patients with CF who may have minimal to profound respiratory or gastrointestinal compromise from this disorder. Treatment is supportive. Maintain the airway, providing oxygen and suction as needed. Humidified oxygen, if available, may help thin mucus and improve respirations.

Multiple Sclerosis

Multiple sclerosis (MS) is a severe, incurable, degenerative disorder involving the central nervous system (brain and spinal cord). Immune cells within the body attack the myelin sheath of certain nerve fibers, ultimately destroying nerve fibers and preventing nerve transmission to other body tissues. It is not entirely clear what causes MS, although some sources describe a connection among genetic predisposition, environmental factors, and possibly nutrition or exposure to a particular virus. According to the National Institute of Neurological Disorders and Stroke, MS is the most common disabling neurologic disease that affects young adults, with a peak incidence between 20 and 40 years of age. It is more common in women than men.⁶

Patients typically present with conditions related to muscle coordination, muscle tone, altered sensation, and altered gait. These patients report periods of varied improvement followed by relapse and progression of the disease. A vast array of signs and symptoms related to neurologic function are possible with MS. Patients may develop problems with the musculoskeletal system such as clumsiness and ataxia, constipation or bladder incontinence, fatigue, decreased sexual performance, extremities that feel heavy or weak, altered sensations (dizziness or vertigo), numbness or tingling in parts of the body, cognitive impairment, disruption of speech or swallowing, and visual impairment. Skin breakdown may result from immobility or poor positioning. Severe manifestations of the disease may render patients bedridden and incontinent. Symptoms can present in many different combinations and last anywhere from several days

to months, often interrupted by periods of absent or reduced symptoms. Life expectancy may be normal, but profound symptoms may cause significant disability or impairment depending on the severity of the disease process.

MS is managed with medications, physical therapy, and counseling. No specific emergency medical services (EMS) treatment for MS exists. Allow additional time for assessment due to cognitive or communication barriers. Because of the disease process, the patient may lack feeling, so the physical exam findings may be difficult to interpret. Other supportive measures include IV hydration, analgesic or muscle-relaxing medications, careful patient positioning, and assisted ventilation when indicated.

Muscular Dystrophy

Muscular dystrophy is a broad term that describes a category of incurable genetic diseases that cause a slow, progressive degeneration of the muscle fibers. In many cases, the destroyed fibers are replaced by adipose (fat) or connective tissue.

Children may present with obvious facial muscle changes, altered gait, delayed psychomotor developmental milestones, and changes in posture. Severe manifestations of certain specific diseases in this group include cardiomyopathy, cognitive impairment, and respiratory compromise. An infant may show obvious signs of muscular dystrophy at birth or have an onset as late as adulthood. In severe cases, profound symptoms or death from muscular dystrophy may occur in children and teenagers. Death typically occurs secondary to cardiac or respiratory dysfunction associated with the disease.

Duchenne muscular dystrophy (DMD), the most common type of muscular dystrophy, is caused by a sex-linked recessive gene that chiefly affects males (1 in every 3,500 to 6,000 male births in the United States).⁷ This disorder is characterized by enlarged heart muscle tissue (dilated cardiomyopathy), heart dysrhythmias, scoliosis (abnormal curvature) of the spine, and gait disturbances. Children with DMD often require the use of a wheelchair by age 15 years.⁸

EMS treatment is primarily limited to careful positioning, supportive treatment, and assisted ventilation in severe cases. Smaller or younger children with muscular dystrophy are typically

relatively easy to examine or transport. Larger children or adults may require additional assistance during movement to or from an ambulance.

Spina Bifida

Spina bifida, also known as myelomeningocele, is a birth defect caused by the incomplete closure of the spinal column during embryonic or fetal development, resulting in an exposed portion of the spinal cord (**FIGURE 38-6**). The opening can be surgically closed, but the child is often left with spinal and neurologic damage. To reduce the occurrences of such disabling birth defects, pregnant women are advised to take vitamin B9 (folic acid). Unfortunately, spina bifida is still one of the most common disabling birth defects in the United States. According to the CDC, one in 2,758 children are born with this defect.⁹ Some patients with spina bifida also have hydrocephalus, which requires the placement of a shunt to drain excessive amounts of cerebrospinal fluid (CSF) from the brain.¹⁰

Be aware that some patients with spina bifida will have partial or full paralysis of the lower extremities and loss of bowel and bladder control; they might also have an extreme allergy to latex products. A supply of latex-free products should be kept on the ambulance to avoid a severe anaphylactic reaction in patients with spina bifida.

Patients with spina bifida will benefit from the same considerations that you offer when you treat a patient with paralysis or a patient who has difficulty moving. Ask patients how it is best to move them before you transport them. Remember to rule

FIGURE 38-6 Spina bifida is one of the most common disabling birth defects in the United States.

© Biophoto Associates/Science Source.

out a fall or other event that may have caused an injury. Check carefully for injuries because patients may not be able to feel them, or the pain of an infiltrated IV solution, for that matter. Also, be aware that patients may have urinary catheters or other aids in place.

Paralysis

Paralysis is the inability to voluntarily move one or more body parts. It may be caused by cerebrovascular accident (stroke), trauma, or birth defects.

Several types of paralysis exist, including the following:

- **Hemiplegia:** Paralysis of one side of the body, possibly from a stroke or head injury
- **Paraplegia:** Paralysis of the lower part of the body, possibly from thoracic or lumbar spinal injury or spina bifida
- **Quadriplegia:** Paralysis of all four extremities and the trunk, possibly from a cervical spine injury

Dysphagia, caused by a partial paralysis of the esophagus, is the inability to swallow. Patients with dysphagia may easily choke or aspirate food and drink, leading to the need for emergency airway interventions. Paralysis of the respiratory muscles causes patients to be completely dependent on a mechanical ventilator or similar device. Interruption of assisted ventilation for even brief periods may have devastating consequences.

Decubitus ulcers (pressure ulcers) are a constant threat for those with paralysis. Patients require frequent mechanical or caregiver assistance to change position. Tissue perfusion to the coccyx region and over bony prominences becomes compromised when external pressure is applied to these areas for a short or long period, as occurs often with bedridden patients. Infection related to pressure ulcers is a significant cause of mortality in these patients.

Patients who have paralysis related to spinal cord injury are at risk for a life-threatening condition known as autonomic dysreflexia. A stressor within the body, sometimes as simple as a full bladder, constipation, or pain, triggers a large release of catecholamines (epinephrine and norepinephrine) from the autonomic nervous system. This release causes vasodilation above the level of the spinal cord injury, as well as massive arterial

FIGURE 38-7 A halo ring/vest combination is used for spinal stabilization after initial management of significant fracture or dislocation.

© Life In View/Science Source.

vasoconstriction. The patient's blood pressure can become dangerously high.

External devices such as halo vests (also called halo rings) are used to immobilize the spine following initial management of significant fractures or dislocations (**FIGURE 38-7**). These devices require additional consideration and coordination while you are moving these patients. Halo vests have substantial weight. It is necessary to support the halo vest without applying any force to it during patient movement. In the event of cardiac arrest, you will typically find an Allen wrench (hex key) attached to the anterior chest portion of the vest for removal only to perform external cardiac compressions.

Words of Wisdom

Do not hesitate to call for additional assistance when transporting a patient with a halo vest, home ventilator, or other piece of equipment that may be bulky and require extra hands to load.

As an AEMT, do not otherwise attempt to reposition or adjust the halo vest.

Patients with paralysis are particularly susceptible to environmental extremes. It is often impossible for these patients to regulate perfusion to the skin. Fluctuations of the autonomic nervous system place patients at risk for hypothermia and (particularly) hyperthermia.

Paralysis does not always entail a loss of sensation. In some cases, the patient will have normal sensation or **hyperesthesia** (increased sensitivity) that may cause the patient to interpret touch as pain in the affected area. Some male patients with a severe spinal cord injury will present with priapism (a prolonged penile erection) unrelated to sexual arousal. Depending on the pattern of sensation loss, the priapism may be associated with discomfort for the patient. For a patient with priapism, maintain privacy and continue to provide supportive care.

Scheduled urinary catheterization is required for many patients with paralysis. Urinary infection, urinary reflux, and autonomic dysreflexia are all possible if patients do not regularly empty the bladder.

Total lifting assistance is typically required for patients with quadriplegia. These patients may or may not need a tracheostomy tube, indwelling urinary catheter, colostomy, or ventilator. You may need to request additional lifting assistance or specialty consultation regarding the ventilator or a similar device.

Patients who have partial or total loss of sensation in the affected limbs cannot tell you when you are hurting them. Take great care to use a gentle touch, especially when lifting or moving patients with paralysis. Ask the patients or their caregivers how to best move them before you transport them. Because paralyzed limbs lack muscle tone, provide IV access and medication on the nonaffected side whenever possible. Check IV sites frequently for infiltration, especially after medication administration.

Words of Wisdom

Patients with significant paralysis can create challenges for EMS providers. Remember to ask for help and know your equipment!

Safety

It takes planning and coordination to move a patient with paralysis without dislodging or compromising extra equipment. You may need to recruit more team members so that you can efficiently move the patient without causing further complications. Strategically placed padding or pillows may help keep the patient more comfortable during transport.

Bariatric Patients

Obesity is a complex condition in which a person has an excessive amount of body fat. It is the result of an imbalance between calories consumed and calories used. The study of **bariatrics** examines the causes, prevention, and treatment of obesity. The solution to the obesity problem may sound relatively simple (reestablish the caloric balance) but unfortunately, the causes of obesity are not fully understood. Oftentimes, this condition may be attributed to low basal metabolic rate or genetic predisposition.

Special Populations

Avoid placing a patient with obesity in the supine position. The excessive weight makes it difficult for the chest to expand. If the patient requires spinal immobilization, then use blankets or other padding to elevate the head from the backboard to facilitate breathing.

According to the CDC, the term *obese* is used when someone has a body mass index (BMI) of 30 kg/m² or higher.¹¹ This is a good general guideline, except in cases where body weight does not correlate to excess fat—for example, in very muscular people. The CDC further defines obesity as follows:

- Class 1: BMI of 30 to <35
- Class 2: BMI 35 to <40
- Class 3: BMI of 40 or higher

Health risks increase with each increase in class. The patient's general quality of life is often negatively affected, and the extra weight can cause a variety of health problems, such as diabetes, hypertension, heart disease, and stroke. Patients with obesity are also susceptible to mobility difficulties, physical injuries, and a variety of musculoskeletal conditions.

Clinical Concerns for the Patient With Obesity

Routine procedures for patients with obesity can be extremely complicated. Airway procedures are made more difficult by a larger tongue, larger head size, and limited neck mobility associated with obesity. Bag-mask ventilation may be ineffective with patients who are in a supine position. Bag-mask ventilation may also become difficult because of poor mask seal or increased resistance due to excess body tissue on the chest wall and abdomen. To perform airway and ventilation procedures, you may need to place the patient in a semi-Fowler position or, if the patient is on a backboard, with the head raised to facilitate optimal chest expansion.

Peripheral IV access is often problematic in patients with obesity. IV attempts are often unsuccessful in extremities and a large neck mass may obscure landmarks for external jugular IV line placement. Many conventional intramuscular (IM) needles will not be able to reach the IM space through excess adipose tissue. Auscultation of heart, lung, or bowel sounds may be more difficult through extra abdominal and chest wall mass. You may also have difficulty determining extent of injury when palpating a particular area due to the excess tissue. If you are unable to determine whether a specific injury exists (eg, a fracture), then treat the patient as if crepitus (a grating or grinding sensation made when two pieces of broken bone are rubbed together) is present.

Special Populations

As an AEMT, you need to advocate for EMS equipment that is capable of safely transporting bariatric patients. Some EMS systems use ambulances with special winches, stretchers, and ramps that allow safe loading and unloading of bariatric patients. Even simple items such as larger blood pressure cuffs, longer injection or intraosseous (IO) needles, or special cervical collars may dramatically improve your ability to provide patient care.

Interaction With Patients With Obesity

People with obesity are often ridiculed publicly and sometimes subjected to discrimination. Patients with obesity may be embarrassed by their condition or fearful of ridicule as a result of past experiences. Some of the negative interactions may have occurred with an insensitive health care professional. As with any patient, work hard to put the patient at ease. Determine the patient's chief complaint, and then communicate your plan to help. Many patients

YOU are the Provider

Part 3

You place the patient onto the stretcher and move him into the ambulance. Once in the back of the ambulance, the patient gradually becomes more alert and oriented. You ask your partner to obtain a baseline set of vital signs, and you begin to establish IV access.

Recording Time: 10 Minutes

Respirations	20 breaths/min
Pulse	104 beats/min; regular
Skin	Warm and dry
Blood pressure	108/86 mm Hg
Oxygen saturation (SpO₂)	99% on 15 L/min
Pupils	Pupils Equal, Round, and Reactive to Light and Accommodation (PERRLA)

5. This patient has a central venous catheter already in place. Should you insert another IV line or use the central line?
6. What is the purpose of the patient's gastrostomy tube?

with severe obesity have a complex and extensive medical history, so mastering the art of conducting a patient interview will serve you well in your interactions with patients with obesity.

Special Populations

As with older adults and pediatric patients, be alert for the possibility of abuse and neglect when treating patients with special needs.

If transport is necessary, plan early for extra help, and do not be afraid to call for more help or specialized equipment. Send a member of your team to find the easiest and safest exit to use. Remember, everyone's safety is at stake! You do not want to risk dropping the patient or injuring a team member by trying to lift too much weight. Patient moves, no matter how simple they may seem, become far more complex with a patient with obesity.

Interaction With Patients With Morbid Obesity

Patients with morbid obesity may overcome mobility difficulties by pulling, rocking, or rolling into a position. The constant strain on their body's structures may leave them with chronic joint injuries or osteoarthritis. When you move a patient with morbid obesity, follow these tips:

- Treat the patient with dignity and respect.
- Ask your patient how best to move before attempting to do so.
- Avoid trying to lift the patient by only one limb, which would risk injury to overtaxed joints.
- Coordinate and communicate all moves to all team members before starting to lift.
- If the move becomes uncontrolled at any point, then stop, reposition, and resume.
- Look for pinch or pressure points from equipment because they could cause significant soft-tissue injuries or a deep vein thrombosis.
- Very large patients will often have difficulty breathing when lying supine. When safe and appropriate to do so, transport patients with the head of the stretcher elevated.
- Many manufacturers now make specialized equipment for patients with morbid obesity, and some areas have specially equipped

bariatric ambulances. Become familiar with the resources available in your area.

- Plan egress routes to accommodate large patients, equipment, and the lifting crew members. Remember: Do no harm!
- Notify the receiving facility early to allow special arrangements to be made before your arrival to accommodate the patient's needs.

Patients With Medical Technology Assistance

Tracheostomy Tubes

A **tracheostomy tube** is a plastic tube used to facilitate breathing. The tube is placed in a tracheal **stoma**, or surgical opening in the neck, and provides a path between the anterior part of the neck and the trachea. The tube can be temporary or permanent and passes from the neck directly into the major airways.

The standard tracheostomy tube has three main components (**FIGURE 38-8**). There is an outer cannula with a flange that helps support and stabilize the device as it passes through the neck. The outer cannula may have a cuff that seals the trachea off from the upper airway. This cuff is inflated

FIGURE 38-8 Some patients require a tracheostomy tube to breathe.

Portex® Blue Line® Ultra Tracheostomy courtesy of Smiths Medical.

through a pilot balloon and valve on the outside of the device. Within the outer cannula is a slightly smaller inner cannula through which the patient is ventilated. The inner cannula has a 15-mm adapter that allows for a bag-mask device or ventilator circuit to be attached. Most, but not all, inner cannulas are capable of being removed for cleaning or in case a plug has developed. The final component of a tracheostomy tube setup is a rigid obturator. This blunt-tipped (rounded) device is curved and long enough to reach to the distal end of the outer cannula. It is used when reinserting the flexible inner cannula. It may also be used to occlude the tracheostomy tube when bag-mask ventilations are being provided over the nose and mouth during an emergency. Some patients use a valve attached to the end of the tracheostomy to help them speak. This valve needs to be removed to suction or ventilate the tracheostomy.

A **laryngectomy** is a surgical procedure in which the larynx is removed, usually because of cancer. The trachea is then curved anteriorly and sewn to tissues of the neck. Bag-mask ventilation through the nose and mouth is ineffective for a patient with a laryngectomy, and you must be careful not to introduce liquids into the stoma. Most patients with a stoma use a stoma cover to act as a filter and prevent mucus from being coughed onto others. A patient with a laryngectomy cannot produce normal speech and must learn to swallow and regurgitate air from the stomach or use an assistive device.

Patients with a tracheostomy tube include those who depend on home automatic ventilators and those who have chronic pulmonary conditions. Because these tubes are foreign to the respiratory tract, the body reacts by building up secretions in or around the tube. The tubes are susceptible to obstruction by mucus plugs or foreign bodies. Routine care that is provided by caregivers includes keeping the inner cannula, as well as the outer cannula, of the tracheostomy tube clean and dry

Special Populations

If you are transporting a child with a tracheostomy in a standard car seat, then avoid using seats with a tray or shield. The tray or shield could come in contact with the tracheostomy and injure the child or block the airway.

TABLE 38-1 DOPE Mnemonic

D	Displaced, dislodged, or damaged tube

P	Pneumothorax
E	Equipment failure (kinked tubing, ventilator malfunction, empty oxygen supply)

© Jones & Bartlett Learning.

and suctioning any secretions. The outer cannula should be changed as needed.

An obstruction of the tracheostomy tube is a life-threatening emergency. Airway management is your first priority. Blood or air may be leaking around the tube, which usually happens with new tracheostomies, and the tube can become loose or dislodged. A useful mnemonic in these situations is DOPE (**TABLE 38-1**). The DOPE mnemonic can help you remember the possible causes of an airway obstruction and correct the problem. Failure to clear an obstructed tracheostomy tube could lead to cardiopulmonary arrest.

It is important to assess for airway patency in all patients, but it is especially important in patients with artificial airways. The basic airway techniques of opening, repositioning, and clearing (especially suctioning) the airway are the most critical steps in improving airway clearance and patency, thereby improving oxygenation and ventilation.

Assess the flow of oxygen, and ensure sufficient oxygen is available in the patient's oxygen system. If you are uncertain about the oxygen flow, then transfer the patient to the flowmeter attached to the main oxygen cylinder in the ambulance.

Words of Wisdom

If a tracheostomy tube becomes plugged, then you can ventilate the patient by deflating the cuff, covering the nose and mouth with a mask, and using the bag-mask device. If you are unable to ventilate the patient through the tracheostomy tube, then plug the tracheostomy stoma and attempt to ventilate the patient in the traditional manner with a bag-mask device. A completely obstructed tracheostomy tube results in hypoxia and leads to cardiac arrest if not cleared quickly.

Occasionally, the opening around the tracheostomy tube may become infected. If suctioning of the tracheostomy tube is necessary, first attempt to use the patient's suction device. It is sized correctly and is usually readily available. If the size of the suction catheter is unknown, estimate the size by doubling the inner diameter of the tracheostomy tube. To determine the length of the suction device, measure the length of a spare tracheostomy tube. If the length of the patient's tracheostomy tube cannot be determined, insert the suction device no more than 1 to 2 inches (3 to 6 cm) deep. The suction unit should be set to 100 mm Hg. You may still need to inject 2 to 3 mL of saline into the tube before suctioning thick tracheal secretions. Do not suction for more than 10 seconds, and do not force the suction catheter into the cannula. Oxygenate before and after the procedure.

To suction and clean a tracheostomy tube, follow the steps in **SKILL DRILL 38-1**.

Special Populations

For cost reasons, home care patients often reuse their suction catheters. If the catheters do not have visible contamination and have been stored in a clean manner, then they are acceptable for use.

Home Oxygen

Patients with certain chronic lung diseases, such as chronic obstructive pulmonary disease, may require long-term home oxygen use. Two types of oxygen delivery systems are used for these patients. The first uses oxygen from compressed gas cylinders, and the second employs an oxygen concentrator.

The compressed gas cylinders used in home oxygen systems are smaller versions of those used on the ambulance. Compressed oxygen cylinders do not require electricity or complex machinery.

Skill Drill 38-1 Suctioning and Cleaning a Tracheostomy Tube

Step 1

Wash your hands, and apply a mask, goggles, and clean nonlatex gloves. Remove the inner cannula and place the device to soak in the proper solution. If the caregiver is not available, then use a mixture of one-half hydrogen peroxide and one-half water. Placing the cannula in plain water is acceptable in short-term situations. (With one-piece tracheostomy tubes, this step is unnecessary.) If the patient is dependent on a ventilator, then have a replacement cannula immediately available.

Step 2

Attach the catheter to negative pressure. Check the suction, and clear the catheter by drawing up a small amount of saline.

Skill Drill 38-1 Suctioning and Cleaning a Tracheostomy Tube (continued)

Step 3

Have the patient take a deep breath, or preoxygenate the patient using the ventilator.

Step 4

Insert the catheter into the trachea without suction. Apply intermittent suction while removing the catheter. Repeat as necessary. Keep the patient well oxygenated during the procedure.

Step 5

Clean the inner cannula with the tracheostomy brush. Rinse, replace, and lock it into place. (Omit this step for a one-piece tracheostomy tube.) Remove your gloves, and wash your hands. Document the procedure and assessment.

During a power outage, the oxygen from a compressed cylinder will still flow. Additionally, the liter flow per minute of oxygen cylinders is limited only by the attached regulator and the amount of gas remaining in the cylinder. The drawbacks of using compressed gas cylinders mainly center around portability and limited supply. Oxygen cylinders can be heavy, bulky, and difficult to transport. Smaller cylinders carry a smaller amount of oxygen, limiting the duration of use. Patients using compressed gas cylinders must have multiple cylinders in reserve

and must coordinate with an oxygen supplier for regular delivery and pickup of cylinders. While oxygen is not flammable, it does support combustion and will cause a fire to burn at much higher temperatures and with much greater intensity.

A home oxygen concentrator is a machine that scrubs the nitrogen from the atmospheric air, leaving behind nearly 100% oxygen that is then compressed and delivered to the patient via oxygen delivery devices (**FIGURE 38-9A**). The compression that home oxygen concentrators can achieve varies

by machine but is generally limited to 10 liters per minute (LPM). The main benefit of an oxygen concentrator is that it can supply unlimited oxygen as long as it is functioning properly and there is a power source. There are also smaller, more portable

A

B

FIGURE 38-9 **A.** Home oxygen concentrator. **B.** Portable oxygen concentrator.

A: © abalcazar/iStock/Getty Images Plus/Getty Images; B: © HKPNC/E+/Getty Images.

oxygen concentrators that can provide patients with increased mobility and freedom of travel, although these units usually can provide only 1 to 3 LPM of flow (**FIGURE 38-9B**). In the event of a power failure, the patient must have a backup compressed gas cylinder to use until power is restored.

Mechanical Ventilators

A mechanical ventilator, also called a respirator, mechanically delivers air to the lungs (**FIGURE 38-10**). Patients who require a mechanical ventilator at home cannot breathe without assistance. Patients requiring a mechanical ventilator may or may not have an underlying respiratory drive because of a congenital defect or a chronic lung disease process. Other patients may have a traumatic brain injury, muscular dystrophy, or another disease process that weakens their ability to breathe and requires a permanent tracheostomy and mechanical ventilator.

If a patient is using a ventilator when you arrive, then assess the patient's chest for synchronous movement with the ventilator. If you have any doubt about ventilator function, then do not be afraid to disconnect the ventilator and begin bag-mask ventilation. To do this, remove the mask from a bag-mask device and directly attach the bag and valve to the tracheostomy tube, which will allow you to ventilate directly through the tracheostomy. Remember, a patient with a tracheostomy does not breathe through the mouth and nose. Therefore, you cannot use a face mask or nasal cannula to treat the patient. A tracheostomy collar is an oxygen delivery device designed specifically for patients with

FIGURE 38-10 A home ventilator.

© ResMed 2010. Used with permission.

FIGURE 38-11 If you do not have a tracheostomy collar, then use a face mask instead.

© Jones & Bartlett Learning. Courtesy of MIEMSS.

tracheostomies. The collar covers the tracheostomy stoma and has a strap that goes around the neck. Tracheostomy collars are usually available in intensive care units, where many patients have tracheostomies, and may not be available in a prehospital setting. If you do not have a tracheostomy collar, then you can improvise by placing a face mask over the stoma (**FIGURE 38-11**). Although the mask is shaped to fit the face, you can usually achieve an adequate fit over the patient's neck by adjusting the strap.

Patients using home mechanical ventilators require assisted ventilation throughout transport. Remember that the patient's caregivers will know how the mechanical ventilator works and will be of great help to you in attaching the bag and valve from a bag-mask device to the tracheostomy tube in preparation for transport. Avoid adjusting home ventilator settings unless you are specifically credentialed to work with the particular device. Again, solicit the help of the patient, family, and caregivers.

Apnea Monitors

When you care for infants with special challenges, you may come across an apnea monitor. The apnea monitor is typically used when an infant is born prematurely, has severe gastroesophageal reflux that causes choking episodes, has experienced an apparent life-threatening event, or if a family history of sudden infant death syndrome (SIDS) exists. Because the central nervous system is not mature in pediatric patients with special challenges, the apnea

monitor is used for 2 weeks to 2 months after birth to monitor the respiratory system. A typical episode of apnea may last only approximately 15 to 20 seconds, during periods of sleep. The apnea monitor is designed to sound an alarm if the infant experiences bradycardia or if an episode of apnea occurs. Chapter 36, *Pediatric Emergencies*, discusses SIDS and apparent life-threatening events in detail.

The apnea monitor is attached with electrodes or a belt wrapped around the infant's chest or stomach. A pulse oximeter may also be used, which measures the oxygenation of the infant's hemoglobin. The apnea monitor will provide a pulse oximetry reading that will assist you in assessing the patient's respiratory status.

The parents or caregivers of pediatric patients with special challenges will be a useful resource to obtain a patient history and the events leading to the call for assistance. Parents and caregivers become very knowledgeable regarding the use of apnea monitors and may be able to provide you and your partner with a computerized printout to share with paramedics or emergency department (ED) personnel. If possible, take the apnea monitor to the receiving hospital with the pediatric patient so that it may be evaluated and any stored information may be retrieved for further analysis.

Words of Wisdom

False alarms are common with apnea monitors and may be caused by movement, loose lead wires, or improperly placed electrodes. When in doubt, follow your local EMS protocols and have the family contact the manufacturer of the device.

Internal Cardiac Pacemakers

An internal cardiac pacemaker is a device implanted under the patient's skin to regulate the heart rate. These devices are typically placed on the nondominant side of the patient's chest so that normal activities are not hindered. In patients who are small or extremely thin, the device may be implanted in the abdomen. In some cases, the pacemaker may also include an automated implanted cardioverter-defibrillator, which monitors the patient's heart rhythm and is able to detect and shock certain cardiac dysrhythmias.

TABLE 38-2 Questions for Patients With Pacemakers or Implanted Defibrillators**Pacemakers**

- What type of heart disorder do you have?
- How long has this device been implanted?
- What is your normal baseline rhythm and heart rate?
- Is your heart completely dependent on the pacemaker device?

Defibrillators

- At what heart rate will the defibrillator fire?
- How many times has the defibrillator shocked you?

© Jones & Bartlett Learning.

Never place defibrillator paddles or pacing patches directly over the implanted device. When you obtain the patient's history during the patient assessment process, you may find it helpful to obtain specific information for the hospital staff, such as the type of cardiac pacemaker (**TABLE 38-2**).

Left Ventricular Assist Devices

A left ventricular assist device (LVAD) is a special piece of medical equipment that takes over the function of one or both heart ventricles in patients with severe heart failure. These types of devices are used either as a bridge to heart transplantation while a donor heart is being located or as a permanent solution for patients who do not qualify for a transplant. LVADs provide a bypass for a left ventricle that is unable to meet the needs of the body. In addition to the multiple LVAD devices available for adult patients with heart failure, there is one approved LVAD designed for children aged 5 to 16 years. Because LVADs provide a continuous flow instead of a pulsatile flow, it may be difficult to palpate a pulse. In such cases, assess perfusion by noting the level of consciousness, skin color, temperature, moisture, and glucose level. Blood pressure is best determined by use of a Doppler ultrasonography and is often unobtainable in the field. Auscultate the chest for a “hum” that indicates the device is working. If no hum is heard, but the patient shows signs of circulation, take the following steps to troubleshoot possible equipment failure:

- If the device has a display screen, look for an alarm code.

- Check cables to ensure everything is connected.
- Check power supply. The patient should have extra batteries. Replace only *one* battery at a time.
- Call the manufacturer's 1-800 number for assistance.

If you encounter a patient with an LVAD, you will primarily provide support measures and basic care while using the caregiver as a resource during transport. The patient should have a “go bag” that must always be transported with the patient. Risk factors associated with the implantation of an LVAD include excessive bleeding following the operation, infection, blood clots leading to strokes, and acute heart failure. Patients with an LVAD are on chronic anticoagulant medications and over time may develop a bleeding disorder similar to hemophilia, which is essentially an acquired von Willebrand deficiency. Additional concerns include epistaxis, gastrointestinal bleeds, and intracranial hemorrhage.

Although medical equipment failure is rare in these cases, be prepared to provide cardiopulmonary resuscitation (CPR) if the situation arises. Keep in mind that the LVAD may be functioning in the absence of a palpable pulse. If you encounter a patient with this device, then contact medical control or follow your local protocols. Understand that chest compressions could dislodge the device or its connections, leaving a hole in the heart, and should be avoided if possible. Medical control may order abdominal compressions for these patients as an alternative. Notify paramedics as soon as possible so that other supportive measures may be initiated.

Words of Wisdom

The manufacturers of special equipment such as an LVAD often include a 1-800 number to call for information specific to patient care. Patients and family members typically carry identification cards with necessary phone numbers and may be able to share this information with you.

External Defibrillator Vest

The external defibrillator vest is a device with built-in monitoring electrodes and defibrillation pads. It is worn by the patient under their clothing. The vest is attached to a monitor that provides

alerts and voice prompts when it recognizes a dangerous rhythm and before it delivers a shock. The device uses high-energy shocks similar to those from an automated external defibrillator (AED), so avoid contact with the patient if the device warns that it is about to deliver a shock.

If the patient is in cardiac arrest, the vest should remain in place while you perform CPR unless it interferes with compressions. Any patient who is wearing a device that has already delivered a shock should be transported to the hospital for further evaluation.

Intra-Aortic Balloon Pumps

As an AEMT, you may assist with transport of patients being treated with an intra-aortic balloon pump (IABP) (**FIGURE 38-12**). IABPs are used to decrease cardiac workload and augment perfusion in patients with cardiogenic shock, structural abnormalities in the heart, myocardial infarction, or following cardiac surgery. You would never be solely responsible for care of a patient with an IABP. It is conceivable, however, that you could accompany a critical care transport team or other health care

provider who is responsible for managing the IABP during interfacility transport of a patient.

IABPs consist of a relatively large machine, connective tubing, monitor cables, and the balloon catheter itself. A cylindrical balloon is inserted through the femoral artery and placed in the aorta, just outside the heart. Tubing connects the balloon catheter to the machine. Monitor leads from the machine are connected to the patient. Movement of both the patient and IABP machine requires careful planning and coordination among members of the transport team.

The balloon is inflated and actively deflated at precise times during the cardiac cycle. During diastole (relaxation of the heart), the balloon inflates, pushing blood forward into systemic circulation. During systole (contraction of the heart), the balloon actively deflates, creating a brief vacuum, and reducing cardiac afterload. This process decreases myocardial oxygen demand, reduces cardiac workload, and improves systemic circulation.

The IABP is bulky and often difficult to move and secure in an ambulance. The transport team must use additional straps to prevent the machine from injuring the patient and/or providers in the event of an ambulance crash. The transport team also needs to take care when handling and securing the connective tubing between the machine and balloon catheter. Accidental removal of the balloon catheter often creates a life-threatening emergency for the patient.

FIGURE 38-12 Intra-aortic balloon pump inflation.

Central Venous Catheters

A central venous catheter, or central line—a venous access device with the tip of the catheter in the vena cava—is used for many types of home care patients, including patients receiving chemotherapy, long-term antibiotic therapy, pain management, total parenteral nutrition, high-concentration glucose solutions, and hemodialysis (**FIGURE 38-13**). Central venous catheters are often located in the chest, upper arm, or subclavicular area.

These devices place the patient at increased risk for cardiovascular complications, including anticoagulation, embolus formation, stasis, air embolus, and obstructed or malfunctioning devices.

Problems associated with central venous catheters may include broken lines, infections around the lines, clotted lines, and bleeding around the line

FIGURE 38-13 Patients who require frequent intravenous medications may have a central line in place.

© Jones & Bartlett Learning. Courtesy of MIEMSS.

or from the tubing attached to the line. If bleeding occurs, then apply direct pressure to the tubing and provide prompt transport to the hospital.

Inspect and secure all external devices before moving the patient, especially when preparing for transport.

Gastrostomy Tubes

Gastrostomy tubes are sometimes referred to as gastric tubes or G-tubes. A gastric tube may be placed when the patient cannot ingest fluids, food, or medications by mouth (**FIGURE 38-14**). Tubes may be inserted through the nose or mouth into the stomach (using nasogastric or orogastric tubes).

In some cases, a gastric tube may be placed surgically through the abdominal wall. Gastric tubes are typically sutured in place and may become dislodged during the patient's normal daily activity. If such a situation arises, then immediately stop the flow of any fluids being infused through the tube. Assess the patient for signs or symptoms of bleeding into the stomach such as vague abdominal discomfort, nausea, vomiting (especially emesis with a “coffee-ground” appearance [old blood]), and blood in emesis.

Patients who have a gastric tube in place may still be at increased risk for aspiration. Always have suction readily available to clear any materials from the patient's mouth and prevent airway problems. Stop the flow of fluids if signs of aspiration are present. To minimize the risk of regurgitation and aspiration, transport the patient while sitting or lying on the right side with the head elevated 30°. Give

FIGURE 38-14 Gastric tubes may be placed through the skin into the stomach for children or adults who cannot adequately be fed by mouth.

© DELOCHE/age fotostock.

supplemental oxygen if the patient has any difficulty breathing.

Patients with diabetes who receive insulin and gastric tube feedings may develop hypoglycemia quickly if the gastric tube feedings are discontinued for any reason. Be alert for an altered mental status or a change in the baseline behavior of your patient. Unless the gastric tube is dysfunctional, dislodged, or partially dislodged, continue the tube feeding and transport the pump with you.

Shunts

Some patients with chronic neurologic conditions may have shunts in place. For example, patients with hydrocephalus will have a shunt. In the case of hydrocephalus, a **shunt** is a tube that extends from the brain down to the abdomen or heart to drain excess CSF that may accumulate around the brain.

A few different types of shunts exist, such as a ventricular peritoneum shunt and a ventricular atrium shunt. A ventricular peritoneum shunt drains excess fluid from the ventricles of the brain into the peritoneum of the abdomen. A ventricular atrium shunt drains excess fluid from the ventricles of the brain into the right atrium of the heart. These shunts keep pressure in the skull from building up.

During the assessment of a patient with a shunt, you will likely feel a device beneath the skin on the side of the head, behind the ear. The device

is a fluid reservoir, and the presence of the device should alert you to the possibility that the patient has an underlying shunt. Should the shunt become dysfunctional, the patient could be predisposed to respiratory arrest.

If a shunt becomes blocked or infected, then changes in mental status and respiratory arrest may occur. Many infections of shunts occur within the first 2 months after the insertion, and most occur within the first year; however delayed infections up to several years have been reported, so providers should not rule out the possibility of a shunt infection simply because a couple months have passed since insertion. A blocked shunt may present as a medical emergency. If the shunt is unable to drain properly, then intracranial pressure may increase and the patient will experience an altered mental status and other signs of increased intracranial pressure.

The signs that a patient is in distress include bulging fontanelles (in infants), headache, projectile vomiting, altered mental status, irritability, high-pitched cry, fever, nausea, difficulty with coordination (walking), blurred vision, seizures, redness along the shunt track, bradycardia, and heart dysrhythmias. Emergency medical care includes airway management and artificial ventilation during transport.

Vagus Nerve Stimulators

According to the Epilepsy Foundation, approximately 150,000 patients are diagnosed with epilepsy each year in the United States.¹² Vagus nerve stimulation is a form of treatment used for seizures that are not controlled with antiepileptic medications or if the patient is not a good candidate for brain surgery. Vagus nerve stimulators stimulate the vagus nerve at predetermined intervals to prevent seizure activity. These devices are used in conjunction with medication to reduce the frequency of seizures. They are not meant to replace medications and are not currently used in children younger than 12 years. Further studies are being done regarding their effectiveness for seizure disorders. The device, which is about the size of a silver dollar, is surgically implanted under the patient's skin. The stimulator can last for up to 6 years or until the battery runs out. If you encounter a patient with this device, then contact medical control or follow your local protocols.

Colostomies, Ileostomies, and Urostomies

A **colostomy** is a surgical opening between the colon and the surface of the body for the purpose of providing drainage of the bowel. An **ileostomy** is

YOU are the Provider

Part 4

Approximately 3 minutes from the hospital, you note that Gary is now fully awake and oriented to his normal status. You ask him about the events surrounding the seizure, but he states that he does not know. On your arrival at the ED, you turn over care to the awaiting staff.

Recording Time: 15 Minutes

Respirations	20 breaths/min
Pulse	96 beats/min

Pupils	PERRLA

7. In which position should you transport this patient?
8. What are the most common causes of developmental disabilities?

a surgical opening between the ileum (part of the small intestine) and the surface of the body to provide drainage of the bowel. The surgical opening is referred to as a stoma. Feces are expelled and collected into a clear external bag or pouch, which is emptied or changed frequently.

If you encounter a patient with a colostomy or ileostomy bag, then assess for signs and symptoms of dehydration if the patient reports diarrhea or vomiting. The area around the stoma is susceptible to infection, so patients and caregivers must be diligent with daily hygiene. Signs of infection include redness, warm skin around the stoma, and tenderness with palpation over the colostomy or ileostomy site.

A **urostomy** is a surgical procedure which connects the urinary system to the surface of the skin,

allowing urine to drain through a stoma in the abdominal wall instead of through the urethra. For example, patients who have had their bladder removed due to cancer require a urostomy.

Contact medical control, or follow your local protocols for the care of a patient with a colostomy, ileostomy, or urostomy bag.

Patient Assessment Guidelines

Interaction with the caregiver of a child or adult with special challenges will be an important part of the patient assessment process. The parents, caregivers, or home health care staff members have become experts on the illness or disability and are trained to use and troubleshoot problems with medical equipment on a daily basis. Assess the patient's baseline vital signs and note any allergies (eg, to medications or latex), medications, and other pertinent medical history. You must first determine the patient's normal baseline status before an assessment of the current condition can be made. It is often helpful to ask, "What is different today?"

Although a patient with special needs may not be able to communicate easily, even patients who cannot speak well or do not speak English may be able to say important words or phrases. Find out how much the patient can speak. Use short, simple questions and simple words whenever possible. Avoid difficult medical terms and point to specific parts of the body as you ask questions.

Words of Wisdom

Signs of potential failure of a gastrointestinal or genitourinary device in the home care setting include abdominal pain or distention, decreased or absent bowel sounds, bladder distention, dysuria, and changes in urinary output or color.

Assessment Pearls

- When responding to a patient with special challenges, do not get tunnel vision. ABCs still take precedence.
- Listen carefully to the caregiver and/or patient. They know much more about the condition and have the proper equipment for the patient.
- Establish a baseline mental status for your patient. Never assume that an altered mental status is normal.
- *Always* assess glucose levels in any patient with an altered mental status.
- Normal evaluation of vital signs may not be possible due to contractures, positioning, and other factors. Ask the caregiver how vital signs are typically measured.
- Establish a baseline oxygen saturation for patients on home oxygen. However, all patients in respiratory distress should be placed on supplemental oxygen at a level appropriate for their level of distress.
- If a tracheostomy tube becomes plugged, consider asking the caregiver to remove the tube and reinsert a new one.

Special Populations

A traumatic event can be especially frightening for patients with special needs, as well as challenging for the provider. Attempt to calm the patient; try to determine if the patient has sight, hearing, or communication problems that could affect assessment. If possible, have a caregiver present during any examination and for patient history.

Home Care

Home care occurs within a patient's home environment. Patients requiring home services represent a spectrum of special health care needs. Patients might be infants or older people, patients with

chronic illnesses, or patients with developmental disabilities. Home care services are commonly needed among patients older than 65 years.

Services offered by home care agencies include, but are not limited to, meal delivery, house cleaning, laundry, yard maintenance, physical therapy, and personal care, including bathing and wound care. Oftentimes, EMS is called to a residence when a home care provider has found the patient injured or has recognized a change in the patient's health status. Home care personnel are an important resource for you when you are obtaining the patient's baseline health status and the history of the present illness or condition. Home care personnel are usually familiar with the patient's surroundings and can obtain any health care documentation or medications that need to be transported with the patient to the hospital.

Hospice Care and Terminally Ill Patients

Unfortunately, some illnesses cannot be cured. As health care providers, you and your team will often be called on to assist a patient who has a terminal illness. The patient may be receiving hospice care at a hospice facility or at home. Hospice care provides comfort care or palliative care (pain medications) during a person's last days. Comfort care and palliative care improve the patient's quality of life before death, allowing the patient to be with family and friends.

Terminally ill patients include patients with illnesses such as cancer, heart and lung failure, end-stage Alzheimer disease, and acquired immunodeficiency syndrome. Many family members who care for chronically ill patients are medically knowledgeable and are often your best source of information and care guidelines.

Terminally ill patients usually need only supportive care. The person may have a displaced urinary catheter or need intervention in a pain crisis. Because terminally ill patients may use a complex array of pain medications, transdermal patches, or self-administered pain management devices, you may need to consult medical direction for guidance in their care.

If you are called to a facility that provides hospice care, then you will need to follow your local protocols, the patient's wishes, or legal documents

Words of Wisdom

Prehospital providers often find it most difficult to work with patients who are in the acceptance stage of the dying process because the patient appears to have given up. It is important to understand that acceptance of an inevitable fate is not "giving up." It often means the person understands the goals of their treatment and is living as fully as possible to the end. Allow patients to do as much as possible for themselves. Talk with the patient or caregiver so that you are aware of what the patient expects from your treatment.

such as a do not resuscitate (DNR) order. Other legal documents that a terminally ill patient may have include a living will and a durable power of attorney. Although these orders require you to withhold life-sustaining treatment in the event of cardiac or respiratory arrest, they do not mean that you should not give any treatment; patients should receive pain medication, supplemental oxygen therapy, nutrition, and hydration as needed based on assessment. See Chapter 3, *Medical, Legal, and Ethical Issues*, for a discussion of legal documents related to end-of-life care.

Even if a DNR order is in place, family members may not understand what to do and they may not be ready to face the death of a loved one. In such cases, obtain a thorough history and compassionately discuss the patient's wishes. Ask to review the DNR order, and contact medical control.

If you are called to a scene in which death is imminent, then the actions you take will have a lasting impact on the family. This is a time when compassion, understanding, and sensitivity are most needed. Some scenes may be chaotic. The family may be having a difficult time coping with the situation, and they may act out with anger and hostility. Treat everyone with compassion and understanding. The other members of your team may be able to separate the people present and speak with them individually to defuse intense emotions and restore order to the situation.

Ascertain the family's wishes about having the patient remain in the home versus transport to the hospital. If a family member requests to accompany the patient, then the person should be allowed to do so. If the family wants the patient to remain at home,

then this request should be honored provided it is in accordance with your local or state protocol.

Local protocols for handling the death of a patient vary, so learn your local or state regulations. The protocols identify whether the coroner needs to be called to report the death and, if so, who is responsible for contacting the coroner. Also determine whether a pronouncement of death is required and, if so, who is responsible for the determination.

Words of Wisdom

A terminally ill patient has the following rights:

- The right to know the truth
- The right to confidentiality and privacy
- The right to consent to treatment
- The right to determine the disposition of their body

Poverty and Homelessness

According to a US Bureau of the Census report, in 2018, 11.8% of the overall US population lived in poverty.¹³ People who live in poverty are unable to provide for all of their basic needs such as housing, food, child care, health insurance, and medication. An impoverished person or family may have housing but may go without food or medication to pay for that housing. Disease prevention strategies such as dental care, good nutrition, and exercise are likely absent, which increases the probability of disease in people who live in poverty.

Homelessness occurs when people are unable to acquire and/or maintain affordable housing.

According to the National Alliance to End Homelessness, nearly 570,000 people experience homelessness on any given night in the United States.¹⁴ The homeless population includes people with mental illnesses, prior brain trauma, survivors of domestic violence, people with addiction disorders, and impoverished families. You may be called to care for a person who has experienced sexual or physical assault, mental health emergencies, overdose, respiratory illness, heat- or cold-related illness, and wound or skin infections.

Part of your job as an AEMT is to be an advocate for patient rights and appropriate care. Your job is to provide emergency medical care and transport patients to the appropriate facility. Remember that under the Emergency Medical Treatment and Active Labor Act (EMTALA), all health care facilities *must* provide a medical assessment and required treatment, regardless of the patient's ability to pay. You can also be an advocate by becoming familiar with the social services resources within your community so you can refer patients to these lifelines.

The evolution of Mobile Integrated Healthcare and Community Paramedicine (MIH-CP) has the ability to benefit many patient populations, including patients with special challenges.¹⁵ As EMS agencies around the country continue to implement these new positions, patients with low-acuity (nonemergency) conditions may be able to be assessed and treated on-scene without transport. In addition, EMS roles may expand to include providing telephone advice to 9-1-1 callers, preventive care, chronic disease management, and post-discharge follow-up.

YOU are the Provider SUMMARY**1. What abnormalities are associated with Down syndrome?**

Down syndrome is caused by a genetic chromosomal defect that can occur during fetal development. Known risk factors for Down syndrome include an increased maternal age and a family history of Down syndrome. A variety of abnormalities are associated with Down syndrome, including a round head with a flat occiput; an enlarged, protruding tongue; slanted and wide-set eyes; congenital heart defects; thyroid problems; vision and hearing problems, and instability of the cervical spine.

2. What type of medical complications may patients with Down syndrome experience?

Patients with Down syndrome are at an increased risk for medical complications including those that affect cardiovascular, sensory, endocrine, musculoskeletal, gastrointestinal, and hematologic systems, as well as neurologic development. Because people with Down syndrome often have large tongues and small oral and nasal cavities, insertion of advanced airways may be difficult. Patients may also have misalignment of teeth and other dental abnormalities. The enlarged tongue and dental anomalies can lead to speech abnormalities as well.

3. How should you interact with a patient with Down syndrome?

It is normal to feel somewhat uncomfortable when initiating contact with a patient with a disability. The best plan of action is to treat the patient as you would any other patient.

4. How should you incorporate the caregiver into your treatment?

Interaction with the caregiver of a patient with special needs is an important part of the patient assessment process. Always speak with the caregiver or family members; they have become experts on the illness or disability.

5. This patient has a central venous catheter already in place. Should you insert another IV line or use the central line?

In most areas, AEMTs are prohibited from using the already established central line. This prohibition exists largely because of the increased rate of infection when central lines are accessed by prehospital providers. The only time that you should manipulate a central line is when it becomes broken and bleeding occurs. If bleeding occurs, then apply direct pressure to the tubing and provide prompt transport to the hospital.

6. What is the purpose of the patient's gastrostomy tube?

The purpose of gastrostomy tubes are for the feeding of patients who cannot ingest fluids, food, or medication by mouth. Typically, these tubes are inserted through the nose or mouth and into the stomach. In some patients, a gastric tube may be placed surgically. Occasionally these tubes may become dislodged during daily activity. If this happens, then you should assess the patient for signs or symptoms of bleeding into the stomach such as vague abdominal discomfort, nausea, vomiting, and hematemesis.

7. In which position should you transport this patient?

Transport this patient in the position of comfort. Transport patients with a gastric tube so they are sitting or lying on the right side with the head elevated 30°. This position will minimize the chance of aspiration.

8. What are the most common causes of developmental disabilities?

A developmental disability may be caused by genetic factors, congenital infections, complications at birth, malnutrition, or environmental factors. Prenatal drug or alcohol use may also cause disability, as in fetal alcohol syndrome. Postnatal causes may include traumatic brain injury or poisoning (such as with lead or other toxins).

Defibrillation	Bleeding Control	Bandaging	Splinting	Other:

Narrative

EMS dispatched to above location for seizure. On arrival, directed to dining room for patient well known to EMS, who had experienced a seizure. Per caregiver, patient had tonic-clonic seizure lasting approximately 90 seconds, ending approximately 2 minutes before our arrival. Caregiver states that patient has Down syndrome and epilepsy. She also states that he has decreased mental capacity and has a G-tube and central line in place. Physical exam of the patient reveals postictal state with ABCs intact. Oxygen via nonrebreathing mask given at 15 L/min. Patient placed on stretcher, secured, and loaded into ambulance. Transport on nonemergency basis to ED. En route: Vitals as above. 20-gauge saline lock established to right forearm. Approximately 3 minutes from ED, patient is alert and oriented to normal status. When asked about events, pt states, "I don't know." On arrival, care and report given to staff without incident.

End of report

Prep Kit

Ready for Review

- As medicine and medical technology continue to improve, the number of children and adults living with chronic diseases or injuries continues to grow. Assess and care for patients with special needs in the same manner as all other patients.
- You may find children and adults who are living at home who depend on mechanical ventilators, IV pumps, or other medical devices to maintain their lives.
- Developmental disability is caused by insufficient development of the brain, resulting in the inability to learn and socially adapt at a normal developmental rate.
- Developmental disabilities include autism spectrum disorder and Down syndrome.
- A patient may have a sensory disability, such as a visual or hearing impairment. Look for signs, such as the presence of eyeglasses, a service animal, hearing aids, or failure to respond to questions.
- Cerebral palsy is a physical disability associated with other conditions such as visual and hearing impairments, difficulty communicating, epilepsy, and intellectual disabilities. Patients may also have an unsteady gait and may require the assistance of a wheelchair or walker.
- Cystic fibrosis is a genetic physical disability characterized by increased production of mucus in the lungs and digestive tract. Pulmonary manifestations include pneumonia, pneumothorax, cough, respiratory distress, and respiratory failure.
- Patients with multiple sclerosis experience an incurable, degenerative breakdown of the central nervous system.
- Muscular dystrophy is a genetic disease characterized by the slow, progressive degeneration of muscle fibers.
- Patients with spina bifida will have either partial or full paralysis of the lower extremities, loss of bowel and bladder control, and an extreme allergy to latex products.
- Several types of paralysis exist, including hemiplegia, paraplegia, and quadriplegia. Paralysis may be caused by cerebrovascular accident (stroke), trauma, or birth defects.
- Patients with obesity may be embarrassed by their condition or fearful of ridicule. If transport is necessary, then plan early for extra help. Identify the easiest and safest exit.
- Patients who depend on home automatic ventilators or who have chronic pulmonary medical conditions may breathe through a tracheostomy tube.
- Patients who require a mechanical ventilator at home cannot breathe without assistance. If the ventilator malfunctions, then disconnect the mechanical ventilator and begin ventilations with a tracheostomy collar or by placing a bag-mask device over the stoma.
- Certain infants may require an apnea monitor. The apnea monitor is designed to sound an alarm if the infant experiences bradycardia or if apnea occurs.
- An internal cardiac pacemaker is a device implanted under the patient's skin to regulate the heart rate.
- A left ventricular assist device (LVAD) is special medical equipment that takes over the function of one or both heart ventricles. LVADs are used as either a bridge to transplantation while a donor heart is being located or as a

permanent solution for patients who do not qualify for a transplant.

- An external defibrillator vest provides alerts and voice prompts when it recognizes a dangerous rhythm and before it delivers a shock.
- Intra-aortic balloon pumps decrease cardiac workload and augment perfusion.
- A central venous catheter is used for many types of home care patients, including patients receiving chemotherapy, long-term antibiotic therapy or pain management, total parenteral nutrition, high-concentration glucose solutions, and hemodialysis.
- Gastrostomy tubes are placed directly into the stomach for feeding in patients who cannot ingest fluids, food, or medication by mouth. These tubes may be inserted through the nose or mouth or placed through the abdominal wall surgically.

- Hydrocephalus shunts are tubes that extend from the brain to the abdomen or heart to drain excess cerebrospinal fluid that may accumulate around the brain.
- A colostomy or ileostomy is a surgical procedure that creates an opening from the small or large intestine to the surface of the body to eliminate waste products. Feces are expelled and collected into a clear external bag or pouch. A urostomy allows for the elimination of urine.
- You and your team may be called on to assist a patient who is terminally ill. Terminally ill patients may be in a hospice facility or at home.
- All health care facilities *must* provide a medical assessment and required treatment, regardless of the patient's ability to pay under the Emergency Medical Treatment and Active Labor Act.

Vital Vocabulary

autism spectrum disorder (ASD) A group of complex disorders of brain development, characterized by impairment of social interaction; may include severe behavioral problems, repetitive motor activities, and impairment in verbal and nonverbal skills.

bariatrics A branch of medicine concerned with the management (prevention or control) of obesity and allied diseases.

cerebral palsy A group of disorders characterized by poorly controlled body movement.

colostomy The surgical procedure to create an opening (stoma) between the colon and the surface of the body to provide drainage of the bowel.

conductive hearing loss Hearing loss caused by a faulty transmission of sound waves.

cystic fibrosis (CF) A genetic disorder of the endocrine system that makes it difficult for chloride to move through the cells; characterized by

increased production of mucus in the lungs and digestive system; also called mucoviscidosis.

developmental disability Insufficient development of the brain, resulting in some level of dysfunction or impairment.

Down syndrome A genetic chromosomal defect that can occur during fetal development and that results in intellectual impairment and certain physical characteristics, such as a round head with a flat occiput and slanted, wide-set eyes.

dysphagia Pain, discomfort, or difficulty in swallowing.

hemiplegia Paralysis of one side of the body, possibly from a stroke or head injury.

hyperesthesia An excessive increase in the sensitivity of an area, particularly in the skin.

ileostomy The procedure to create an opening (stoma) between the ileum (part of the small

intestine) and the surface of the body to provide drainage of the bowel.

laryngectomy A surgical procedure in which the larynx is removed.

multiple sclerosis (MS) A severe, incurable degenerative disorder involving the central nervous system (brain and spinal cord).

muscular dystrophy A category of incurable genetic diseases that cause a slow, progressive degeneration of the muscle fibers.

obesity A complex condition in which a person has an excessive amount of body fat; the result of an imbalance between calories consumed and calories used; defined as a body mass index of greater than or equal to 30 kg/m².

paraplegia Paralysis of the lower part of the body, possibly from thoracic or lumbar spinal injury or spina bifida.

quadriplegia Paralysis of all four extremities and the trunk, possibly from a cervical spine injury.

sensorineural deafness A permanent lack of hearing caused by a lesion or damage of the inner ear.

shunt A passageway that allows fluid to move from one part of the body to another or to a dialysis machine; in cases of hydrocephalus, a tube that drains excess cerebrospinal fluid from the brain to another part of the body outside of the brain, such as the abdomen; lowers pressure in the brain.

spina bifida A developmental defect in which a portion of the spinal cord or meninges may protrude outside of the vertebrae and possibly even outside of the body, usually at the lower third of the spine in the lumbar area.

stoma A surgical opening in the body that connects an internal structure to the skin, such as in the neck to connect the trachea directly to the skin.

tracheostomy tube A tube inserted through the hole created by a tracheostomy, used to facilitate breathing.

urostomy The procedure to create an opening (stoma) between the urinary system and the surface of the skin, allowing urine to drain through a stoma in the abdominal wall instead of through the urethra.

SECTION 10

Chapter 39

Transport Operations

NATIONAL EMS EDUCATION STANDARD COMPETENCIES

EMS Operations

Knowledge of operational roles and responsibilities to ensure patient, public, and personnel safety.

Principles of Safely Operating a Ground Ambulance

- Risks and responsibilities of emergency response (pp 1885–1887, 1892–1919)
- Risks and responsibilities of transport (pp 1899–1900, 1902–1913)

Air Medical

- Safe air medical operations (pp 1913–1919)
- Criteria for utilizing air medical response (pp 1915–1916)

Medicine

Applies fundamental knowledge to provide basic and selected advanced emergency care and transportation based on assessment findings for an acutely ill patient.

Infectious Diseases

Awareness of

- A patient who may have an infectious disease (pp 1901–1902)
- How to decontaminate equipment after treating a patient (pp 1887–1892)

Assessment and management of

- How to decontaminate the ambulance and equipment after treating a patient (pp 1901–1902)

KNOWLEDGE OBJECTIVES

1. Describe the nine phases of an ambulance call, including examples of key tasks that advanced emergency medical technicians (AEMTs) perform during each phase. (pp 1885–1901)
2. Describe the medical equipment carried on an ambulance, including examples of supplies that are included in each main category of the ambulance equipment checklist. (pp 1887–1892)
3. Provide examples of the safety and operations equipment carried on an ambulance, including how each item might be used by AEMTs in an emergency. (pp 1892–1894)
4. Explain the importance of performing regular vehicle inspections. (pp 1894–1895)
5. List the specific parts of an ambulance that should be inspected daily. (pp 1894–1895)
6. Describe the minimum information that should be gathered by the emergency medical services (EMS) dispatcher for every emergency call. (pp 1895–1896)
7. Provide examples of some high-risk situations and hazards that may affect the operation of the ambulance and the safety of its passengers during both pretransport and transport. (pp 1896–1897)
8. Discuss specific considerations that are required for ensuring scene safety, including personal safety, patient safety, and traffic control. (pp 1897–1899)
9. Describe the key elements related to patient information that must be included in the patient care report upon patient delivery to the hospital. (pp 1899–1900)

PHOTO: © Hypervision Creative/Shutterstock.

10. Summarize the tasks that must be completed by AEMTs at the completion of an ambulance call. (pp 1900–1901)
11. Define the terms cleaning, disinfection, high-level disinfection, and sterilization. (p 1901)
12. Discuss the guidelines for driving an ambulance safely and defensively, including key steps EMS personnel can take to improve safety while en route to the scene, the hospital, and the station. (pp 1902–1904)
13. Describe the elements that dictate the use of emergency warning lights and siren to the scene and to the hospital and the factors required to perform a risk-benefit analysis regarding the use of these devices. (p 1905)
14. Give examples of the specific, limited privileges that are provided to emergency vehicle drivers by most state laws and regulations. (pp 1906–1911)
15. Explain why using police escorts and crossing intersections pose additional risks to EMS personnel during transport, including the special considerations related to each. (pp 1912–1913)
16. Describe the capabilities, protocols, and methods for air medical operations. (pp 1913–1915)
17. Describe key scene safety considerations when preparing for the medical evacuation of a patient by helicopter, including establishing a landing zone, mitigating onsite hazards, and approaching the aircraft. (pp 1915–1919)

SKILLS OBJECTIVES

1. Demonstrate how to perform a daily inspection of an ambulance. (pp 1894–1895)
2. Demonstrate how to clean and disinfect the ambulance and equipment during the postrun phase. (pp 1901–1902)
3. Demonstrate how to use defensive ambulance driving techniques. (pp 1902–1904)
4. Demonstrate how to operate safely around an air ambulance. (pp 1917–1919)

Introduction

During the late 1700s, Napoleon Bonaparte commissioned one of the most advanced professional emergency medical patient care systems in the world. At that time, horse-drawn ambulances were already in use in major cities throughout the United States (**FIGURE 39-1**). American hospitals initiated professional ambulance services during the late 1860s. Ambulance attendants traveled with limited medical supplies, including brandy, a few tourniquets, assorted bandages and sponges, basic splinting materials, and blankets.

Today's ambulances have come a long way since the first horse-drawn ambulances of the 1700s. Modern ambulances are stocked with standard medical supplies. Many are equipped with state-of-the-art technology, including defibrillators and monitors that can transmit information directly to the emergency department (ED), blood and oxygen testing equipment, automatic ventilators, automated cardiopulmonary resuscitation (CPR) machines, global positioning systems (GPS), mobile data terminals (MDTs), and computer-aided dispatch (CAD) consoles. Even

FIGURE 39-1 Horse-drawn ambulances were used in major cities throughout the United States beginning in the late 1700s.

© National Library of Medicine.

when you follow all safety guidelines, today's emphasis on technology places you in great danger while driving to calls. Although technology can aid in tasks such as directing the route and mode of response of the ambulance, it is also distracting. Therefore, the use of technology potentially increases your risk for crashes.

This chapter discusses ambulance design and how to equip and maintain an ambulance. It focuses

on the techniques and judgment that you will need to learn to drive an ambulance or ambulance service vehicle, which include parking considerations, emergency vehicle control and operation, the effects of weather on driving, and common hazards that are encountered while driving an ambulance. Finally, it describes how to work safely with air ambulances.

Street Smarts

Anything can be a distraction while driving. It is imperative that you work with your partner to eliminate the need for the driver to take their attention off the road. For example, the provider in the passenger seat should operate the GPS or MDT so the driver can focus on driving. From reading call notes from a CAD to requesting information regarding scene safety over the radio, these necessary distractions can all serve as a dangerous, if not fatal, mistake.

Emergency Vehicle Design

An **ambulance** is a specialized vehicle that is used for treating and transporting sick and injured patients. The first motor-powered ambulance was introduced in the late 1800s. For many decades after that, a hearse was the vehicle that was most often used as an ambulance, because it was the only vehicle with room enough for a person to lie down. Few supplies were carried onboard, and little space was available for attendants.

The hearse-ambulance has gone the way of its horse-drawn predecessor. Modern ambulances are designed according to strict government regulations

based on the National Fire Protection Association's *Standard for Automotive Ambulances*, otherwise known as NFPA 1917.¹ The standards themselves are based in large part on suggestions from the ambulance industry, including emergency medical services (EMS) personnel. One of the most significant developments in ambulance design has been the enlargement of the patient compartment. Another development is the use of specialized **first-responder vehicles**, which allow firefighters, law enforcement officers, and other providers to respond initially to the scene with EMS equipment and to treat the sick and injured until an ambulance arrives.

The modern ambulance is a vehicle for emergency medical care that has the following features:

- A driver's compartment (cab)
- A patient compartment that can accommodate two EMS providers and usually two supine patients (one patient on the stretcher, and one patient on the bench or area designed with swivel seats to accommodate a long backboard) positioned so at least one of the patients can receive CPR during transport
- Equipment and supplies used to provide emergency medical care at the scene and during transport, to safeguard personnel and patients from hazardous conditions, and to carry out basic extrication procedures
- Two-way radio communications so ambulance personnel can speak with the dispatcher, the receiving facility, public safety authorities, and online medical control
- Design and construction that ensure maximum safety and comfort. For example, the **chassis** is the structural framework of the ambulance.

YOU are the Provider

Part 1

At 2100 hours, your ambulance is dispatched to a standby for a structure fire with possible entrapment. En route to the call, you note that your partner is driving aggressively through city traffic and motorists are slamming on their brakes in front of you. To avoid causing a collision, you advise him to leave more room between the ambulance and other vehicles you are approaching. He slows down and you arrive on scene 5 minutes after you were dispatched.

1. What are the nine phases of an ambulance call?
2. Which of the nine phases of an ambulance call is the most important?
3. What are some potential distractions that may be found inside of the ambulance?

Each state establishes its own standards for licensing or certifying ambulances; however, most states use the federal specifications (NFPA 1917) that cover three types of basic ambulance designs (**FIGURE 39-2** and **TABLE 39-1**).

The six-pointed **Star of Life** emblem (**FIGURE 39-3**) identifies vehicles as ambulances. It is often affixed to the sides, rear, and roof of the ambulance. Local or state regulatory authorities determine what emblems may be displayed on the side of an ambulance. **FIGURE 39-4** illustrates some of the required features of a licensed or certified ambulance.

Phases of an Ambulance Call

An ambulance call has three main phases divided as follows: prior to the scene (preparation, dispatch, en route), at the scene (arrival at the scene, transfer of patient to ambulance, transport to receiving facility), and after the scene (arrival at receiving facility, en route to station, postrun). These are shown in **TABLE 39-2**. These nine phases address the ambulance and its team, and their roles in a response to

TABLE 39-1 Basic Ambulance Designs

Type I	Conventional, truck cab-chassis with a modular ambulance body that can be transferred to a newer chassis as needed
Type II	Standard van, forward-control integral cab-body ambulance
Type III	Specialty van cab with a modular ambulance body that is mounted on a cutaway van chassis

TABLE 39-2 Phases of an Ambulance Call	
Prior to the Scene	1. Preparation for the call
	2. Dispatch
	3. En route to the scene
At the Scene	4. Arrival at the scene
	5. Transfer of the patient to the ambulance
	6. En route to the receiving facility (transport)
After the Scene	7. Arrival at the receiving facility (delivery)
	8. En route to the station
	9. Postrun

© Jones & Bartlett Learning.

a medical emergency. The details of patient care are not included in these nine phases.

Preparation for the Call

An important part of preparing for the call is to ensure that equipment and supplies are in the proper place and ready for use and that the ambulance is

FIGURE 39-5 Store equipment and supplies in the ambulance according to how urgently and how often they are used.

© Jones & Bartlett Learning. Courtesy of MIEMSS.

in good working order with adequate fluid levels, fuel, and tire pressure. Some services have special personnel to stock and clean the ambulances. Items that are missing or that do not work are of no use to you or the patient. Furthermore, many EMS items have never been rigorously tested under field conditions and could turn out to be expensive mistakes. For this reason, new equipment should be placed on an ambulance only after approval by the medical director. Additionally, you must receive proper instruction on the use and care of any new piece of equipment before using it in the field. As a general rule, the more complex a piece of equipment is and the harder it is to learn to use, the more likely it is to malfunction during an emergency.

Equipment and supplies should be durable and, to the extent possible, standardized. This makes it easy to quickly exchange equipment with other ambulances or with the ED, thus, saving time during patient transfer.

Store equipment and supplies in the ambulance according to how urgently and how often they are used (**FIGURE 39-5**). Give priority to items that are needed to care for life-threatening conditions,

including equipment for airway management, artificial ventilation, and oxygen delivery. Place these items within easy reach of the head of the primary stretcher. Place items for cardiac care, control of external bleeding, and monitoring of blood pressure at the side of the stretcher. Make sure batteries are fresh and equipment is functioning properly. For example, the most common cause of a malfunctioning automated external defibrillator (AED) is a dead battery.

Storage cabinets and kits should open easily. They should also close securely so they do not fly open while the ambulance is in motion. Cabinet doors and drawers should be transparent so you can quickly identify the contents inside; if they are

not transparent, then clearly label each storage container.

Medical Equipment

As an advanced emergency medical technician (AEMT), you have access to a large variety of medical equipment and supplies, far more than can be described here. Certain items on the ambulance must be available at all times, as dictated by state and jurisdictional requirements.

Basic Supplies

TABLE 39-3 lists the common supplies carried on ambulances. These supplies include basic items

TABLE 39-3 Ambulance Equipment Checklist

Basic Supplies	Airway and Ventilation Equipment
Pillows and pillowcases	Infection control kits (goggles, masks, waterproof gowns)
Sterile sheets	Oropharyngeal airways and nasopharyngeal airways of various sizes
Blankets	Advanced airway supplies, if local protocol permits (laryngeal mask airway, Combitube, King airways), with secondary placement confirmation devices
Towels	Bag-mask devices (adult, child, and infant)
Disposable emesis bags or basins	Mounted suction unit and a portable suction unit
Boxes of disposable tissue	Assorted oxygen delivery devices (adult and pediatric), including continuous positive airway pressure (CPAP) equipment
Bedpan (optional)	Pulse oximeter and end-tidal carbon dioxide (ETCO ₂) supplies
Urinals (one each for men and women; optional)	Oxygen supply units (both portable and installed)
Blood pressure cuffs (pediatric, adult, large adult)	Disposable humidifier (for mounted oxygen system)
Stethoscope	Basic Wound Care Supplies
Disposable drinking cups	Trauma shears
Unbreakable container of water	Sterile sheets
Wet wipes	Sterile burn sheets
Chemical cold/hot packs	Adhesive tape in several widths
Sterile irrigation fluid	Self-adhering, soft roller bandages, 4 in. × 5 yd (10 cm × 5 m)
Restraining devices	
Plastic bags for waste or severed parts	
Hypoallergenic nitrile, vinyl, or other disposable hypoallergenic gloves (various sizes)	
Sharps container	
Set of hearing protectors	

(continues)

TABLE 39-3 Ambulance Equipment Checklist (*continued*)

Self-adhering, soft roller bandages, 2 in. × 5 yd (5 cm × 5 m)	• Umbilical tape or sterilized cord • Small rubber bulb syringe • Towels • Gauze sponges • Sterile gloves • Sanitary napkins • Plastic bag • Baby blanket • Baby stocking cap
Sterile dressings, gauze, 4 × 4 in. (10 × 10 cm)	
Sterile dressings, abdominal or laparotomy pads, usually 6 × 9 in. (15 × 23 cm) or 8 × 10 in. (20 × 25 cm)	
Sterile universal trauma dressings, usually 10 × 36 in. (25 × 91 cm), folded into 9 × 10 in. (23 × 25 cm) packages	
Sterile, occlusive, nonadherent dressings (aluminum foil sterilized in original package)	
Occlusive dressings, or chest seals	
Assortment of adhesive bandages	
Wound-packing supplies	
Tourniquets	
Splinting Supplies	Automated External Defibrillator
Adult-size traction splint	Semiautomated defibrillation equipment
Child-size traction splint	Patient Transfer Equipment
A variety of arm and leg splints, such as inflatable, vacuum, cardboard, plastic, foam-covered wire-ladder or aluminum alloy, or padded board (the number and type of splints should be determined by state regulations and your medical director)	Wheeled ambulance stretcher
A variety of triangular bandages and roller bandages	Wheeled stair chair
Short backboard/short immobilization device	Other devices also carried on ambulances include:
Long backboard	• Scoop stretcher • Portable/folding stretcher • Flexible stretcher • Transfer tarp or slide board • Basket stretcher
Cervical collars in an adjustable size or a variety of sizes	Medications and Other Supplies
Head immobilization devices	Activated charcoal
Childbirth Supplies	Drinkable water and cups
Emergency obstetric kit, including:	Oral glucose
• Surgical scissors • Hemostats or special cord clamps	Oxygen
	Supplies for irrigating the skin and eyes
	Nebulized beta agonists and anticholinergics for patients who are wheezing
	Aspirin, nitroglycerin, naloxone, and epinephrine, as well as other medications within local protocol
	DuoDote or other regional equipment, depending on the area and local protocol
	Portable radio or cell phone

© Jones & Bartlett Learning.

such as disposable gloves and sharps containers, airway and ventilation equipment, basic wound care supplies, splinting supplies, childbirth supplies, an AED, patient transfer equipment, medications, and other supplies such as a snakebite kit or regional supplies.

Airway and Ventilation Equipment

The ambulance should carry the following equipment for airway management:

- Oropharyngeal airways for adults, children, and infants

- Nasopharyngeal airways for adults and children
- Oxygen delivery devices (adult and pediatric), including continuous positive airway pressure (CPAP) equipment
- Equipment for advanced airway procedures, if your service is authorized by state regulations and the medical director to perform these

It is important that the ambulance carry two portable artificial ventilation devices that operate independently of an oxygen supply: one for use in the ambulance and one for use outside the ambulance or as a spare. These devices include disposable pocket masks and bag-mask devices. Bag-mask devices capable of oxygen enrichment and, when attached to an oxygen supply with the oxygen reservoir in place, able to supply almost 100% oxygen should also be carried. Masks for these devices come in a variety of sizes, from neonatal to adult, and are necessary materials to carry on the ambulance. Oxygen-powered devices are also available to provide ventilation to a patient, but these may quickly deplete available oxygen sources. Follow local guidelines in identifying the specific ventilation equipment carried on the ambulance.

The ambulance should carry both portable and mounted suctioning units (**FIGURE 39-6**). These units must be powerful enough to provide an air-flow of 30 L/min at the end of the tube and a vacuum of 300 mm Hg when the tube is clamped. The suctioning force must be adjustable for use on infants and children. The suctioning units should include large-bore, nonkinking suction tubing and semirigid tips. The installed unit should include a suction yoke, an unbreakable collection canister, suction catheters, water for rinsing the suction tips, and suction tubing. All of these components must be easily accessible when you are sitting at the head of the stretcher. The suction tubing must reach the patient's airway, regardless of the patient's position. All components of the suctioning unit must be disposable or made of material that is easily cleaned and **decontaminated**.

The ambulance should carry at least two oxygen supply units: one portable and one mounted onboard the vehicle. The portable unit should be located near a door or in the jump kit, for easy use outside the ambulance. It should have a minimum capacity of 500 L of oxygen and be equipped with

A

B

FIGURE 39-6 The ambulance should carry both a mounted suctioning unit (**A**) and a portable suctioning unit (**B**).

© Jones & Bartlett Learning.

a yoke, pressure gauge, flowmeter, oxygen supply tubing, nonrebreathing mask, and nasal cannula. This unit must be able to deliver oxygen at a variable rate between 1 and 15 L/min. At least one additional portable 500-L cylinder should be kept on the ambulance. Many services equip the backup cylinder with its own yoke, gauge, regulator, and tubing so that it can be used for a second patient.

The mounted oxygen unit should have a capacity of 3,000 L of oxygen (**FIGURE 39-7**). It should also be equipped with visible flowmeters that are capable of delivering 1 to 15 L/min and that are accessible when you are at the head of the stretcher. Oxygen masks, with and without nonrebreathing bags, should be transparent, disposable, and available in sizes for adults, children, and infants.

Ambulance services that often transport patients on runs lasting longer than 1 hour should

FIGURE 39-7 An oxygen unit with a capacity of 3,000 L of oxygen should be mounted in the ambulance.

© Jones & Bartlett Learning. Courtesy of MIEMSS.

consider using a disposable, single-use humidifier for the mounted oxygen system, which reduces the patient's risk of infection. On runs of less than 1 hour, humidification is usually unnecessary.

CPR Equipment

A **CPR board** provides a firm surface under the patient's torso so you can give effective chest compressions (**FIGURE 39-8A**). It also assists in establishing an appropriate degree of head tilt (**FIGURE 39-8B**). Only a few ambulances across the country carry this item. If you do not have a CPR board, then you can place a backboard or short backboard under the patient on the stretcher. Use a tightly rolled sheet or towel to raise the patient's shoulders 3 to 4 inches (8 to 10 cm); this technique will also keep the patient's head in a position of maximum backward tilt and keep the shoulders and chest in a straight position. Do not use this roll to hyperextend the neck if you suspect a spinal injury.

Mechanical devices that operate on compressed gas and deliver chest compressions and ventilations are also available.

A

B

FIGURE 39-8 A. A cardiopulmonary resuscitation (CPR) board may be carried on the ambulance. **B.** A patient on a CPR board has the appropriate degree of head tilt for effective artificial ventilation.

A: Courtesy of Ferno Washington, Inc.; **B:** © Jones & Bartlett Learning. Courtesy of MIEMSS.

Basic Wound Care Supplies

Basic supplies for dressing open wounds should be included on the ambulance. These supplies include a pair of trauma shears; sterile sheets; sterile burn sheets; adhesive tape in several widths; self-adhering, soft roller bandages; sterile dressings; gauze; abdominal or laparotomy pads; sterile universal trauma dressings; sterile, occlusive, nonadherent dressings (aluminum foil sterilized in original package); an assortment of adhesive bandages; and tourniquets.

Splinting Supplies

Examples of supplies for splinting fractures and dislocations that may be carried on ambulances

FIGURE 39-9 Supplies for splinting fractures and dislocations should be carried on the ambulance.

© Jones & Bartlett Learning.

are shown in **FIGURE 39-9**. These supplies include both an adult-size and a child-size traction splint; a variety of arm and leg splints, such as inflatable, vacuum, cardboard, plastic, foam wire-ladder, or padded board; a variety of triangular bandages and roller bandages; a short backboard; a backboard; head immobilization devices; and cervical collars in either an adjustable size or a variety of sizes.

Childbirth Supplies

You must carry at least one sterile emergency obstetric kit (**FIGURE 39-10**) that includes the supplies listed in Table 39-3, including a pair of surgical scissors, hemostats or special cord clamps, umbilical tape or sterilized cord, a small rubber bulb syringe, towels, gauze sponges, pairs of sterile gloves, plastic wrap, sanitary napkins, a plastic bag, a baby stocking cap, and a baby blanket.

AED

Semiautomated defibrillation equipment or manual monitor/defibrillators that have automated external defibrillation capability, as permitted by regulations and the local medical director, should always be carried on the ambulance (**FIGURE 39-11**).

Patient Transfer Equipment

Each ambulance should carry the following patient transfer equipment:

- A primary wheeled ambulance stretcher
- A wheeled stair chair for use in narrow spaces
- A backboard

FIGURE 39-10 A sterile emergency obstetric kit must be carried on the ambulance.

© Mark C. Ide.

FIGURE 39-11 Every ambulance should carry an automated external defibrillator.

LIFEPAK CR® Plus AED or LIFEPAK CR® Plus defibrillator courtesy of Physio-Control. Used with Permission of Physio-Control, Inc., and according to the Material Release Form provided by Physio-Control.

- A short backboard or short immobilization device

You should be able to tilt the head of the stretcher upward to at least a 60° angle semisitting position (**FIGURE 39-12**). Stretchers must be provided with fasteners to secure them firmly to the floor or side of the ambulance during transport. Stretcher restraints should be capable of holding the stretcher in place in case the vehicle rolls over. Make certain that the wheeled stretcher is properly locked into position, because injuries can occur to the patient and you if the stretcher becomes loose while the ambulance is in motion. Make sure there are at least two restraining devices for the patient, such as deceleration or stopping straps over the shoulders,

FIGURE 39-12 The wheeled ambulance stretcher should be locked into place at an appropriate height.

Courtesy of Angulo, Raul A.

to prevent the patient from continuing to move forward in case the ambulance suddenly slows or stops. Regardless of the equipment used, it is important to perform proper lifting techniques to avoid injuries. Chapter 6, *Lifting and Moving Patients*, discusses the proper lifting and moving of patients.

Words of Wisdom

It may seem inconvenient or time consuming to apply shoulder straps when securing the patient to the stretcher. While you are securing the patient, explain how important it is for the person's safety. Using all straps is an essential habit, much like applying your own seat belt when riding in the cab.

Words of Wisdom

You can move the patient to the ambulance in different ways, depending on the injury or illness. It is easier and safer to have some patients walk to the ambulance, rather than trying to use a stretcher. For patients with spinal injuries, the use of a backboard or other immobilization device is advised. If you do not suspect any spinal injuries, then transport patients with respiratory conditions in a sitting position to allow for optimal comfort and safety.

FIGURE 39-13 A portable jump kit should contain practically anything you will need during the first 5 minutes with the patient.

© Jones & Bartlett Learning.

Medications

It is important that the ambulance carry valid and appropriate medications. Be certain that you have the telephone number and radio frequency of on-line medical control or the local poison control center with you on the ambulance. The back of your clipboard is a good place to keep this information.

The Jump Kit

The ambulance must be equipped with a portable, durable, and waterproof jump kit that you can carry to the patient (**FIGURE 39-13**). Think of the **jump kit** as the “5-minute kit,” containing anything you might need in the first 5 minutes with the patient except for the semiautomated external defibrillator, possibly the oxygen cylinder, and portable suctioning unit. The jump kit must be easy to open and secure. **TABLE 39-4** lists the items that are typically contained in a jump kit.

Safety and Operations Equipment

In addition to medical equipment, a properly stocked ambulance carries several kinds of equipment for responder safety, rescue operations, and locating emergency scenes. To do the job effectively, EMS personnel will need the following equipment:

- Personal protective equipment (PPE) that meets the standards of the American National Standards Institute (ANSI)

TABLE 39-4 Items Carried in a Jump Kit

- Nitrile, vinyl, or other disposable gloves
- Face shield or mask with goggles
- Triangular bandages
- Pair of trauma shears
- Adhesive tape in various widths
- Universal trauma dressings
- Self-adhering soft roller bandages, 4 in. × 5 yd (10 cm × 5 m) and 2 in. × 5 yd (5 cm × 5 m)
- Oropharyngeal airways in adult, child, and infant sizes^a
- Bag-mask device with masks for adults, children, and infants^a
- Pulse oximeter
- Blood pressure cuff
- Glucometer
- Stethoscope
- Penlight
- Sterile gauze dressings, 4 × 4 in. (10 × 10 cm)
- Sterile dressings (abdominal pads), 6 × 9 in. (15 × 23 cm) or 8 × 10 in. (20 × 25 cm)
- Adhesive strips
- Oral glucose
- Activated charcoal
- Other medications as allowed by local protocols
- Intravenous supplies (administration set, bag of fluid)^b

^a These items might be carried in a separate airway kit, along with the portable oxygen cylinder.

^b Medications are carried in a separate drug box and depend on local protocols for the level of care; therefore, specific medications are not listed here.

© Jones & Bartlett Learning.

- Equipment for work areas
- Preplanning and navigation guides
- Extrication equipment

Personal Safety Equipment

Along with your ANSI Class 2 reflective vest, always carry PPE that allows you to work safely in a limited variety of hazardous or contaminated situations. These situations include the edges of a structural fire or explosion, vehicle extrication incidents, and in crowds. The equipment should protect you from exposure to blood and other potentially infectious body fluids. Note that you will not be equipped to face all hazardous materials (hazmat) and other exposure situations that you may encounter; this is the job of specially trained hazmat technicians and response teams. Your PPE might include the following:

- Face shields
- Gowns, shoe covers, caps

FIGURE 39-14 The ambulance should have a weatherproof compartment that can be reached from outside the patient compartment. It should hold equipment for safeguarding patients and responders, controlling traffic and bystanders, and illuminating work areas.

© Jones & Bartlett Learning. Courtesy of MIEMSS.

- Turnout gear
- Helmets with face shields or safety goggles
- Safety shoes or boots
- Tactical vest or body armor

Equipment for Work Areas

A weatherproof compartment that you can reach from outside the patient compartment should hold equipment for safeguarding patients and responders, controlling traffic and bystanders, and illuminating work areas (**FIGURE 39-14**). The following items are recommended:

- Warning devices that flash intermittently or have reflectors (road flares are not acceptable because they can pose an additional hazard, such as ignition of flammable liquids or gases)
- Two high-intensity, rechargeable halogen flashlights (20,000 candlepower) of the stand-up type
- Fire extinguisher, dry chemical, type ABC (5-pound [2-kg] minimum)
- Hard hats or helmets with face shields or safety goggles
- Portable floodlights

Preplanning and Navigation Guides

GPS devices and MDTs are standard equipment in modern ambulances. Store the addresses of area

hospitals, nursing homes, and other key locations for easy access. Enter the address of the hospital into the GPS device before initiating transport to the hospital. Remember that if you are driving the vehicle, never turn your attention away from the road to use a device of any type. Make sure you also have detailed street and area maps in the driver's compartment of the ambulance, along with directions to key locations. Become familiar with the roads and traffic patterns in your town or city so you can plan alternative routes to frequent destinations. Pay particular attention to ways around frequently raised bridges, congested traffic, or blocked railroad crossings. Often, switching to an alternative route will save more time than driving faster. Also, be familiar with special facilities within your regional operating area such as other medical facilities, airports, arenas and stadiums, and chemical or research facilities that might pose unusual challenges (staging areas may be predefined for emergency operations).

Extrication Equipment

A weatherproof compartment outside the patient compartment should contain equipment that is needed for basic extrication, even if an extrication and rescue unit is readily available. **TABLE 39-5** lists the items that may be included in the compartment.

If rescue and extrication services are not readily available, then additional equipment may be needed. See Chapter 40, *Vehicle Extrication, Special Rescue, and Hazardous Materials*, for more information.

Personnel

Every ambulance must be staffed with at least one EMS provider in the patient compartment whenever a patient is being transported; two EMS providers are strongly recommended. Some services may operate with a civilian (non-EMS) driver and a single EMS provider in the patient compartment.

Daily Inspections

Being fully prepared means you and your team must inspect both the ambulance and equipment daily to ensure all items are in proper working order. The ambulance inspection should include the following:

- Fuel level
- Oil level

TABLE 39-5 Basic Extrication Equipment

- 12-in. (30-cm) wrench, adjustable, open-end
- 12-in. (30-cm) screwdriver, standard square bar
- 8-in. (20-cm) screwdriver, #2 Phillips head
- Hacksaw with 12-in. (30-cm) carbide wire blades
- Vise-grip pliers, 10 in. (25 cm)
- 5-lb hammer with 15-in. (38-cm) handle
- Fire ax with 24-in. (61-cm) handle
- Wrecking bar with 24-in. (61-cm) handle (may be a combination tool with a hammer and ax)
- 51-in. (130-cm) crowbar, pinch point
- Bolt cutter with 1-in. to 1.25-in. (3-cm) jaw opening
- Folding shovel, pointed blade
- Tin snips, double action, 8 in. (20 cm) minimum
- Gauntlets, reinforced, leather covering past midforearm, one pair per team member
- Rescue blanket
- Ropes, 5,400-lb (2,449-kg) tensile strength in 50-ft (15-m) lengths in protective bags
- Mastic knife (able to cut seat belt webbing)
- Spring-loaded center punch
- Roll of duct tape (for application to window prior to center punch use)
- Pruning saw
- Heavy-duty shoring (cribbing) blocks, 2 × 4 in. (5 × 10 cm) and 4 × 4 in. (10 × 10 cm), various lengths

© Jones & Bartlett Learning.

- Transmission fluid level
- Engine cooling system and fluid levels
- Batteries
- Brake fluid
- Engine belts
- Wheels and tires, including the spare, if available. Check inflation pressure and look for signs of unusual or uneven wear.
- All interior and exterior lights
- Windshield wipers and fluid
- Horn
- Siren
- Air conditioners and heaters
- Ventilation system
- Doors. Make sure they open, close, latch, and lock properly.
- Communication systems, vehicle and portable
- All windows and mirrors. Check for cleanliness and position.

Check all medical equipment and supplies daily, including all the oxygen supplies, the jump kit, splints, dressings and bandages, backboards

Words of Wisdom

Because the mechanical aspects of emergency work such as driving and moving patients strongly impact your safety and that of others, your service should have specific procedures for daily inspections. Following them protects you physically, and documenting your compliance is an important legal protection. These procedures should call for dating and either signing or initialing the check sheets and for storing them in a secure location. For more information, see Chapter 4, *Communications and Documentation*.

and other immobilization equipment, and the emergency obstetrics kit. Is the equipment functioning properly? Are the supplies clean? Are enough supplies available? Perform checks of all battery-operated equipment each day according to the manufacturer's guidelines, including the AED. Rotate the batteries according to an established schedule and the manufacturer's guidelines and ensure that all charging cables are connected.

Safety Precautions

A final part of the preparation phase is reviewing safety precautions. Follow these precautions, which include standard traffic safety rules and regulations, on every call. Check safety devices, such as the seat belts in the cab and patient compartment, to ensure they are in proper working order.

Dispatch

The dispatch center must be easy to access and in service 24 hours per day (**FIGURE 39-15**). It may be operated by the local EMS agency or by a shared service that also covers law enforcement and the fire department. The dispatch center might serve only one jurisdiction, such as a single city or town, or it might be an area or regional center serving several communities or an entire county. In either case, it should be staffed by trained personnel who are familiar with the agencies they are dispatching and the geography of the service area. For every emergency call, the dispatcher should gather and record the following minimum information:

- The nature of the call
- The name, present location, and callback telephone number of the caller
- The location of the patient or patients

FIGURE 39-15 The dispatcher is the key communications link throughout all nine phases of the ambulance run.

© Jones & Bartlett Learning. Courtesy of MIEMSS.

- The number of patients and some idea of the severity of their conditions
- Any other special challenges or pertinent information about hazards or weather conditions

Words of Wisdom

Your local telecommunicators and dispatchers are a valuable resource. They work hard to determine the exact circumstances of the incident to which you are responding and relay that information to you. However, their ability to provide useful information is limited by the person calling 9-1-1. Irrelevant, inaccurate, or incomplete information may be obtained and relayed to the emergency responders. Take note of all information provided to you, but do not allow yourself to develop tunnel vision or decrease your level of situational awareness. Be sure to clarify all information received and ask for additional information as needed. There is no replacement for your critical thinking skills and situational awareness on scene.

Many areas implement emergency medical dispatch, a sophisticated system that allows the dispatcher to provide the caller with instructions for patient care before the ambulance arrives. The emergency medical dispatcher follows a set of guidelines to determine the type of information given and then guides the caller through basic care such as bleeding control or CPR.

En Route to the Scene

In many ways, the en route or response phase of the call is the most dangerous for responders. Crashes

that involve emergency vehicles cause many serious injuries among EMS personnel. (Techniques to make vehicle operation safer will be discussed later in this chapter.) As you and your partner prepare to respond to the scene, fasten your seat belts and shoulder harnesses before you move the ambulance. At this point, inform dispatch that your unit is responding and confirm the nature and location of the call. This is also an excellent time to ask for any other available information about the location. For example, you might learn that the patient is located on the third floor or that the best door to use is around the side of the house.

When responding to a violent crime or if your dispatcher has detected the possibility that the scene is not safe for you to enter, you may be requested to stage your ambulance away from the scene while law enforcement officers respond to secure the scene. If you are requested to stage your ambulance, make sure it is a safe distance from the scene. “Safe distance” does not mean 100 feet down the street from the residence to which you are responding. Bystanders or family members who see your ambulance stopped and not proceeding immediately into the scene may become agitated or violent because they want you to respond and render immediate care, even if the scene is not safe. Consider staging out of sight of

the scene, even a few streets away. If there is only one road into or out of the neighborhood to which you are responding, do not stage on that road. If the person who originally assaulted a patient is fleeing the scene, you do not want to provide this person with the opportunity to delay or harm emergency responders. Follow local protocols and be aware of how your agency responds to potentially unsafe scenes.

While en route, your team should prepare to assess and care for the patient. Review dispatch information about the nature of the call and the location of the patient. Assign specific initial duties and scene management tasks to each team member, and decide what type of equipment to take initially. Depending on your local operation procedures, you may also decide which stretcher to bring to the patient.

Arrival at the Scene

On arrival at the incident, perform a scene size-up. After you complete your scene size-up, report to dispatch the nature of the incident (if this is part of your local protocols). If additional units are en route, then provide dispatch with your size-up information to help determine whether the additional units should continue to the scene. For example, if you determine the patient is potentially violent during

YOU are the Provider

Part 2

On arrival you see members of the fire department fighting a fully engulfed structure fire. Law enforcement is also on scene directing traffic around the incident. After making contact with the incident commander, you stage your ambulance in the designated area. Suddenly, you hear a shout. You see several firefighters carrying an adult man out of the structure. They place him in a safe area and return to the fire because of the potential for additional victims. The patient has obvious burns to his face, chest, and arms, and you note the following findings:

Recording Time: 1 Minute

Appearance	Poor; blisters on his face
Level of consciousness	Unresponsive
Airway	Soot around his mouth; singed nasal hair
Breathing	Slow and shallow
Circulation	Weak, rapid radial pulses

4. While en route, how should you prepare to assess and care for the patient?
5. What equipment do you need to carry to the patient's side?

FIGURE 39-16 If you are the first responder to arrive on the scene of a mass-casualty incident, then report to dispatch and ask for additional units, such as rescue or hazmat units, as needed.

© Mark Terrill/AP Photo.

your scene size-up, then law enforcement personnel should continue to the incident scene.

If you are the first responder to arrive on the scene of a mass-casualty incident (MCI), then inform dispatch that you have arrived and give a brief report of what you see. Quickly estimate the number of patients and report the need for additional units, such as a heavy rescue unit or a hazmat team (**FIGURE 39-16**). Do not enter the scene if any safety hazards are present. If safety hazards are present at the scene, then move the patient out of danger before you begin care. Emergency moves are discussed in Chapter 6, *Lifting and Moving Patients*.

Immediately size up the scene by using the following guidelines:

- Look for safety hazards to yourself, your partner, bystanders, and your patient or patients.
- Evaluate the need for additional units or other assistance.
- Determine the mechanism of injury (MOI) in trauma patients or the nature of the illness in medical patients.
- Evaluate the need to immobilize the spine.
- Take standard precautions. The type of emergency medical care that you expect to give will dictate the PPE you wear.

If you are not the first responder to arrive at the scene of an MCI, then locate and communicate with the designated incident commander (**FIGURE 39-17**). MCIs involve complex organization of personnel under the incident command system. In this system, you may be assigned a specific role

FIGURE 39-17 At a mass-casualty incident, follow the instructions from the incident commander. Your assigned role may include assisting with triage, treating patients, or loading patients for transportation to the hospital.

© John Sartin/Shutterstock.

by the incident commander, such as beginning the triage process, assisting in treating patients, or loading patients for transportation to the hospital. The incident command system is discussed in Chapter 41, *Incident Management*.

Safe Parking at a Crash Scene

In assessing the situation, you must decide where to park the ambulance. Pick a position that will allow for efficient traffic control and flow around a crash scene. Do not park alongside the scene, because you may block the movement of other emergency vehicles and/or impede your own exit. Instead, park before or after the scene, depending on whether other responders have arrived. The first emergency vehicle should create a barrier between the scene and traffic traveling in the same direction as the lane of traffic you are occupying. If arriving after other emergency vehicles, the ambulance should be positioned about 100 ft (30 m) beyond the scene, thereby preventing your vehicle from being blocked in when transporting a patient. If the street has not been completely closed and there is a driveway or parking lot adjacent to the scene, consider parking the ambulance there.

FIGURE 39-18 If other responders, such as firefighters or law enforcement officers, are on scene first, park the ambulance about 100 feet (30 m) past the scene on the same side of the road to allow an unobstructed departure path.

© Jones & Bartlett Learning.

If your vehicle is the first to arrive on scene, you should park about 100 ft (30 m) before the scene on the same side of the road in the fend-off position (**FIGURE 39-18**). In the fend-off position, the ambulance is parked at a diagonal angle, with the front wheels turned away from the scene. This position helps to block the scene and create a safety barrier within which you can operate. If a vehicle strikes the rear of an ambulance parked in the fend-off position, it is more likely to be deflected outward than directly into the area of the crash, where emergency personnel are working. Distracted drivers or poor weather conditions may create dangerous scenarios in which a vehicle may inadvertently drive into the scene at full speed. Assume someone may collide with your vehicle and strike personnel on the scene. Having a large emergency vehicle as a safety barrier may provide you with a cushion of space that could save your life.

Words of Wisdom

When you park at a scene at night, leave on the emergency warning lights but turn off your headlights. Utilize parking lights to prevent impairing the vision of motorists in oncoming traffic.

Stay away from any fires, explosive hazards, downed wires, and structures that might collapse. If your ambulance is blocking part of the roadway, then leave on the emergency warning lights. Some

motorists tend to drive toward emergency vehicles with flashing red or red and white lights. Within these safety guidelines, try to park your ambulance as close to the scene as possible to facilitate emergency medical care. If necessary, you can temporarily block traffic to unload equipment and to load patients quickly and safely. Do not block traffic any longer than is absolutely necessary. Finally, lock all doors when leaving the ambulance and ensure the designated driver has the keys.

Safety

When operating at an incident on any roadway, use caution when exiting the ambulance, wear protective equipment, and maintain a high level of situational awareness. Even with all of the emergency vehicles parked appropriately on a scene, distracted drivers may still drive straight into an emergency vehicle. On a roadway, it is important to wear reflective safety vests or turnout gear. If you are retrieving equipment from the side compartment of your ambulance, you may be virtually invisible if you are not wearing your reflective vest. Even attentive drivers may have difficulty seeing areas around the emergency vehicles with all of the warning lights on.

Traffic Control at a Crash Scene

After ensuring your own safety, your first responsibility at a crash scene is to care for the patients. Only after all the patients have been treated and the

emergency situation is under control should you be concerned with restoring the flow of traffic. If the police do not arrive quickly at the scene, then you might need to temporarily provide traffic control.

The main objectives of traffic control are to warn other motorists, to prevent additional crashes, and to ensure an orderly traffic flow so emergency medical care of the injured is not interrupted. Under ordinary circumstances, traffic control is difficult. A crash or disaster scene presents serious additional challenges. Passing motorists often slow down and stare, paying little attention to the roadway in front of them. Some curiosity seekers may park down the road and return on foot, creating still other hazards. As soon as possible, place appropriate warning devices, such as reflectors, on both sides of the crash.

Transfer of the Patient to the Ambulance

Many patients have said that one of the most frightening parts of being suddenly ill or injured is the ambulance ride to the hospital. A patient who is already anxious may be made more so by a fast, bumpy ride with a siren blaring. Sometimes, such a ride is truly lifesaving. However, in most cases, excessive speed is unnecessary and dangerous and may prevent the provider in the back of the ambulance from rendering appropriate care. It is necessary that the patient be safely transported to an appropriate medical care facility in the shortest practical time. Speed is no substitute for common sense and defensive driving techniques. In almost every case, you will provide life-saving care right where you find the patient, before moving the patient to the ambulance. You may then begin less critical measures, such as bandaging and splinting. Next, package the patient for transport by securing the patient to a device such as a backboard, a scoop stretcher, or the wheeled ambulance stretcher. Finally, move to the ambulance and properly lift the patient into the patient compartment.

No matter how careful the ambulance driver may be, riding to the hospital while lying down on a stretcher can be uncomfortable and even dangerous. Be sure to secure the patient with at least three straps across the body (**FIGURE 39-19**). Use deceleration or stopping straps over the shoulders to prevent the patient from continuing to move forward in case the ambulance suddenly slows or stops. This

FIGURE 39-19 Secure patients appropriately to ensure their safety during transport.

© Jones & Bartlett Learning.

step is especially important if the patient is lying flat or secured to a backboard.

En Route to the Receiving Facility (Transport)

Inform dispatch when you are ready to leave with the patient. Report the number of patients you have and the name of the receiving hospital. Even though you have already assessed and treated the patient, continue to monitor the patient's condition en route. These ongoing assessments may reveal changes in the patient's vital signs and overall condition. Recheck the patient's vital signs en route. The frequency of checking vital signs depends on the situation, but checking them every 15 minutes for a stable patient and every 5 minutes for an unstable patient is a practice that many services use. In addition, it is important to continually reassess the patient's clinical situation and record and address new conditions and the patient's responses to earlier treatment.

At this time, also contact the receiving hospital. Inform medical control about your patient or patients and the nature of the problem or problems. Depending on the number of AEMTs on your team and how much emergency medical care the patient needs, you might also want to begin working on your patient care report (PCR) while en route.

Finally, and most importantly, do not abandon the patient emotionally. Do not become so involved in paperwork and reassessments that you ignore the patient's fears. You are there to help the patient, so use this time to offer reassurance. Some patients,

such as very young or older people, may benefit from added attention during transport. Be aware of your patient's level of need.

Arrival at the Receiving Facility (Delivery)

Inform dispatch as soon as you arrive at the hospital. Then follow these four steps to transfer the patient to the receiving hospital:

1. Report your arrival to the triage nurse or other arrival personnel.
2. Physically transfer the patient from the stretcher to the bed directed for your patient.
3. Present a complete verbal report at the bedside to the nurse or physician who is taking over the patient's care.
4. Complete a detailed PCR, obtain the required signatures, and leave a copy with an appropriate staff member. Electronic reports are commonly used. Your service should have a method for printing or sending electronic reports as well as obtaining electronic signatures.

The PCR should include a summary of the history of the patient's current illness or injury with pertinent positives and negatives, the MOI, and findings on your arrival. In addition, list the vital signs and briefly mention relevant past medical or surgical history, as well as information regarding medication and allergies. Also, be sure to include any treatment given in the prehospital setting and its effect.

Documentation & Communication

As a prehospital emergency provider, you are in a unique position to tell a vital portion of the patient's story. Your verbal report and written documentation paint a picture of the prehospital environment that can have a significant impact on the patient's course of care at the hospital. A patient who was involved in a vehicle crash and appears to have only minor skin injuries may have critical internal injuries. Your description of the vehicle, along with possible speed on impact, may be the deciding factor for the patient to receive immediate care rather than being relegated to the waiting area. Never underestimate the importance of your role in the continuum of care.

While at the hospital, you may be able to restock any items that were used during the run, such as oxygen masks or dressings and bandages (**FIGURE 39-20**). Remember, though, that your priority is transfer of the patient and patient information to the hospital staff. Restocking the ambulance comes second.

En Route to the Station

After you leave the hospital, inform dispatch whether you are in service and where you are going. As soon as you are back at the station, do the following:

- Clean and disinfect the ambulance and any equipment that was used, if you did not do so before leaving the hospital (**FIGURE 39-21**).
- Restock any supplies you did not get at the hospital.

FIGURE 39-20 After transferring the patient and relating patient information to the hospital staff, you should restock any items that were used during the run.

Postrun

During the postrun phase, complete and file any additional reports and again inform dispatch of the status, location, and availability of the unit.

Each team member is responsible for maintaining the ambulance so that it is safe and available on a moment's notice. As discussed previously, this responsibility means you should perform routine inspections. Use a written checklist to document any needed repairs or the replacement of equipment and supplies.

Street Smarts

The postrun phase is also the appropriate time to debrief following the call. Discuss the initial situation encountered on scene, strengths identified by the team's performance during the call, and opportunities for improvement regarding clinical knowledge, assessment, and skill proficiency. This debriefing process ideally should follow every call and should be conducted in a professional, nonjudgmental manner while respecting each team member's input.

Ambulance Cleaning and Disinfection

One way to protect patients is by complying with work restriction guidelines. Reporting for work when you have a sore throat or the flu is not in the best interests of your patients or your coworkers.

Words of Wisdom

Providers should be aware of current CDC guidelines regarding COVID-19 vaccination and work restrictions if they experience any symptoms suggestive of COVID-19 infection or exposure to infected persons.

Another way to protect patients from nosocomial infections is to keep the ambulance interior and its equipment clean and disinfected. It is important that you know the meanings of the following terms:

- **Cleaning.** The process of removing dirt, dust, blood, or other visible contaminants from a surface or equipment.
- **Disinfection.** The killing of pathogenic agents by directly applying a chemical made for that purpose to a surface or equipment.

- **High-level disinfection.** The killing of pathogenic agents by using potent means of disinfection.
- **Sterilization.** A process, such as the use of heat, that removes all microbial contamination.

When you are cleaning equipment, select cleaning solutions to fit the equipment category:

- **Critical equipment.** Items that come in contact with mucous membranes, such as laryngoscope blades and surgical forceps, endotracheal tubes, and Combitubes. High-level disinfection (that is, use of Environmental Protection Agency (EPA)-registered chemical "sterilants") is the minimum level for this equipment.
- **Semicritical equipment.** Items that come in direct contact with intact skin; these include stethoscopes, blood pressure cuffs, splints, and pneumatic antishock garments. Clean with solutions that have a label claiming to kill hepatitis B virus. Bleach and water at 1:100 dilution meets this requirement.
- **Noncritical equipment.** Cleaning surfaces, floors, ambulance seats, and work surfaces. EPA-registered hospital-grade cleaner or bleach and water mixture is effective for this equipment.

General cleaning routines need to be listed in the department's exposure control plan.

A basic rule is to ensure that the following 12 steps are taken after every call:

1. Immediately strip used linens from the stretcher after use, and place them in a plastic bag or in the designated receptacle in the ED.
2. Discard in an appropriate receptacle all disposable equipment used for care of the patient that meets the definition of medical waste as dictated by your state. Most items will be considered general trash. Discard disposable equipment that is bloody or contaminated by body fluids in a biohazard container approved by the Occupational Safety and Health Administration (OSHA). Discard non-contaminated disposable equipment used for care of the patient according to OSHA and local guidelines.
3. Wash all contaminated areas with soap and water. Scrub blood, vomitus, and other

substances from the floors, walls, and ceilings with soap and water. For disinfection to be effective, you must first clean the ambulance. (You can use a 10% solution of bleach in water to clean the ambulance after any contamination.)

4. Disinfect all reusable equipment used in the care of the patient. For example, properly clean and disinfect stethoscopes, blood pressure cuffs, and pulse oximetry probes.
5. Clean the stretcher with either a germicidal/virucidal solution registered by the EPA, or bleach and water at 1:100 dilution.
6. Clean up any spillage or other contamination that occurred in the ambulance with the same germicidal/virucidal or bleach/water solution.
7. Clean the outside of the ambulance as needed.
8. Replace or repair broken or damaged equipment without delay.
9. Replace any other equipment or supplies that were used.
10. Refuel the ambulance if the fuel tank is below required reserves. Check the oil level each time the ambulance is refueled.
11. Create a schedule for routine full cleaning of the vehicle.
12. Have a written policy or procedure for cleaning each piece of equipment. Refer to the manufacturer's recommendations as a guide.

Safety

Remember to assess for the following hazards while operating an ambulance:

- Downed power lines
- Leaking fuels or fluids
- Smoke or fire
- Broken glass
- Trapped or ejected patients
- MOI

Before leaving the scene:

- Ensure that hazards have been addressed.
- Ensure that all equipment has been properly stored or disposed of.
- Ensure that the scene has been turned over to the appropriate authority (eg, law enforcement, fire department).

Defensive Ambulance Driving Techniques

According to the National Highway Traffic Safety Administration, approximately 4,500 motor vehicle crashes involving an ambulance occurred every year between 1992 and 2011. Of these crashes, 65% resulted in damage to property only; 34% resulted in one or more injuries; and 1% resulted in one or more fatalities.² These statistics show the significant effect of traffic crashes on pedestrians, motorists, ambulance passengers, and EMS personnel. Learning how to properly operate the ambulance is just as important as learning how to care for patients when you arrive on the scene. As you will learn, ambulances do not handle the same as personal vehicles. Ambulances require a longer braking time and stopping distance. In addition, the weight of the ambulance is unevenly distributed, which makes it more prone to rollover. These factors greatly increase the chance that a crash may occur. An ambulance that is involved in a crash delays patient care at a minimum, and may take the lives of the EMS providers, other motorists, or pedestrians at worst. The following section is provided to introduce you to safe driving techniques; however, you cannot become a proficient and safe ambulance driver without specialized training and practice. You are strongly encouraged to participate in an emergency driving program, such as the National Association of Emergency Medical Technicians (NAEMT) EMS Vehicle Operator Safety (EVOS) course, designed for the EMS vehicle operator, and those offered through your EMS organization, before operating an emergency vehicle.

Driver Characteristics

Not everyone who drives a motor vehicle is qualified to drive an ambulance. In some states, you must successfully complete an approved emergency vehicle operations course before you are allowed to drive the ambulance on emergency calls. In any state, due diligence and caution are important characteristics, as are a positive attitude about your ability and tolerance of other motorists.

One basic requirement is physical fitness. Crashes occur as a result of physical impairment of the driver. Do not drive if you are taking medications that may cause drowsiness or slow your reaction

times. These medications include cold remedies, analgesics, and tranquilizers. Of course, never drive or provide emergency medical care after drinking alcohol. Fatigue can also play a prominent role in crashes, so it is imperative to get as much rest as possible during free times. Driving alone may also be a factor during long transports.

Another requirement is emotional fitness. Do not take emotions lightly. People's personalities can change once they are behind a steering wheel. Emotional maturity and stability are closely related to the ability to operate under stress. Other drivers may have wildly different reactions when they encounter your ambulance. It is up to you to operate the vehicle in a safe fashion and never make any judgments or maneuvers based on an emotional response. In addition to knowing exactly what to do, you must be able to do it under difficult conditions.

Having the proper attitude is very important. Never get behind the wheel of an ambulance thinking that you can drive in any manner that pleases you. Great responsibility is placed on the driver of an ambulance.

In addition to training and experience, the good judgment and knowledge that you need to drive an

ambulance require practice. Remember, even the best drivers can benefit from practice.

Safe Driving Practices

The first rule of safe driving in an ambulance is that speed does not save lives; good emergency medical care does. The second rule is that the driver and all passengers must wear seat belts and shoulder restraints at all times. These devices are the most important items of safety equipment on every ambulance.

Learn how your ambulance responds to **acceleration** (increasing speed), cornering, and **deceleration** (decreasing speed) under various

Words of Wisdom

Speed does not save lives; good emergency medical care does! Your partner cannot provide adequate patient care while being thrown around the patient compartment. Drive carefully and call out upcoming movements, such as, "Sharp turn to the left," or "Railroad tracks."

YOU are the Provider

Part 3

As you perform your primary survey of the patient, you note his respirations are slow and shallow and he has blisters on his chest and arms. The skin in unburned areas is pink. You direct your partner to begin positive-pressure ventilations while you complete your assessment. Because of the extent of his burns and obvious airway compromise, the decision is made to transport this patient via air ambulance. Law enforcement personnel establish a safe landing zone in the parking lot of a local elementary school. You and your partner load the patient into the ambulance to continue treatment and await the arrival of the helicopter.

Recording Time: 8 Minutes

Respirations	6 breaths/min, shallow
Pulse	124 beats/min, thready
Skin	Burns to the face, chest, and arms
Blood pressure	96/52 mm Hg
Oxygen saturation (SpO₂)	86% on room air
Pupils	Equal but sluggish to respond

6. What are some advantages of using an air ambulance?
7. What are some disadvantages of using an air ambulance?
8. What factors must you take into consideration when creating a landing zone?

TABLE 39-6 Guidelines for Safe Ambulance Driving

1. Select the shortest and least congested route to the scene at the time of the dispatch.
2. Avoid routes with heavy traffic congestion; know alternative routes to each hospital during rush hours.
3. Avoid one-way streets; they may become clogged. Do not drive against the flow of traffic on a one-way street unless absolutely necessary.
4. Watch carefully for bystanders as you approach the scene. Curiosity seekers rarely move out of the way.
5. Park the ambulance in a safe place after you arrive at the scene. If you park facing into traffic, turn off your headlights so that they do not impair the vision of oncoming motorists unless your headlights are needed to illuminate the scene. If the ambulance is blocking part of the road, then leave on your emergency warning lights to alert oncoming motorists; otherwise, turn them off.
6. Drive within the speed limit while transporting patients, except in the rare extreme emergency.
7. Go with the flow of the traffic.
8. Always exercise due regard for people and property.
9. Always drive defensively.
10. Always maintain a safe following distance. Use the “4-second rule”: stay at least 4 seconds behind another vehicle in the same lane.
11. Maintain an open space in the lane next to you as an escape route in case the vehicle in front of you stops suddenly.
12. Use your siren if you turn on the emergency warning lights.
13. Always assume that other motorists will not hear the siren or see your emergency warning lights.

© Jones & Bartlett Learning.

conditions. For example, disc booster brakes make braking more efficient but increase sway. When you drive an ambulance on a multilane highway, stay in the far left (passing) lane whenever possible. This tactic allows other motorists to move over to the right when they see or hear the ambulance approach.

TABLE 39-6 lists additional guidelines to follow when you are en route to a call.

Use of Safety Restraints

Standard operating procedures should mandate that everyone in the ambulance use seat belts, not just the patient. Wear restraints en route to the scene and whenever you are not performing direct patient care. Remember to properly restrain the patient. Do not transport children on the stretcher unless they are properly restrained. It is not advisable to use adult seat belts for children. Many pediatric transport devices are available; use them when appropriate.

Studies show that fewer than one-half of all AEMTs wear seat belts while the ambulance is in emergency mode, and few AEMTs wear lap belts in the rear compartment while patient care is being rendered. If you must remove your seat belt to care for the patient, then fasten it again as soon as possible. As mentioned previously, unrestrained or improperly restrained patients and medical equipment (especially portable oxygen tanks) may become airborne during a crash and place you and your patient at an additional risk. Secure all equipment and cabinets, as well as the patient and any passengers accompanying the patient.

Excessive Speed

Even in extreme life-and-death emergencies, excessive speed is not indicated. In most instances, if you properly assess and immobilize the patient at the scene, then excessive speed during transport is unnecessary and undesirable. Regardless of the

situation, never travel at a speed that is unsafe for the given road conditions.

Excessive speed, in addition to being unnecessary, does not increase a patient's chance of survival. More often, using excessive speed while driving to and from the scene has resulted in crashes in which the AEMT, the patient, and occupants of other vehicles are killed. It also makes it very difficult for the AEMT attending to the patient to be able to provide emergency medical care because of the rough ride typically created by the excessive speed and maneuvering. Excessive speed also reduces the driver's reaction time and increases the time and distance needed to stop the ambulance. Although many state laws allow emergency vehicles to travel beyond the posted speed limits in emergencies, these laws offer little or no protection against prosecution should the driver become involved in a crash. The legal ramifications of driving an emergency vehicle will be covered later in this section.

Siren Risk-Benefit Analysis

Whether responding to a call or transporting a patient from the scene to the hospital, the decision to activate the emergency warning lights and siren will depend on several factors such as local protocols, the patient's condition, and the anticipated clinical outcome of the patient. Some local protocols require that all responders to the scene use their emergency warning lights and sirens, whereas other EMS systems incorporate response modes based on the information received from dispatch. Regardless of your jurisdictional requirements, as the driver of the ambulance, you need to evaluate the risk versus the benefit of your response mode. Numerous studies have been performed to determine whether the emergency warning lights and siren save time getting to the patient or getting the patient from the scene to the hospital. The findings of these studies show that only minimal time is saved.

Three basic principles govern the use of the warning lights and siren on an ambulance:

1. The unit, to the best of your knowledge, must be on a true emergency call.
2. Audible and visual warning devices must be used simultaneously.
3. The unit must be operated with due regard for the safety of all others, on and off the roadway.

As an AEMT, you also need to take into account the patient's condition before activating the emergency warning lights and siren. For example, patients who have experienced a seizure may have another seizure as a result of the rapid flash pattern of the emergency lighting. In cases such as this, it may be preferable to transport your patient without activating the emergency warning lights and siren in an effort to minimize external stimuli and to avoid making your patient's condition worse. If you have to use the siren, then warn the patient before you turn it on. Lights and siren should be used only when the highest-trained provider caring for the patient believes there to be a true benefit to the patient based on possible time saved by a shorter transport time and the patient's clinical condition. Be especially mindful not to increase the speed of the ambulance just because the siren is in use.

The siren may also have a psychological effect on motorists. Recognizing this will help you become aware of your or other motorists' tendencies to drive faster in the presence of a siren. Although a siren signifies a request for motorists to yield the right-of-way, motorists do not always yield.

Safety

Driving emergently in an ambulance with the lights and siren activated will likely cause you to experience a rush of adrenaline. Your respiratory rate and heart rate will increase, and your palms may become sweaty. This physiologic response is natural, but it may cause you to have limited focus and impair your ability to judge distance or the potential actions of others. Understanding your body's response to driving with lights and siren can help you to mitigate the associated risks. Take a deep breath and proceed with caution, remembering the guidelines for safe ambulance operation.

Never assume that your emergency warning lights and siren will allow you to drive through a congested area without stopping or slowing down. Slow down to ensure that all drivers are stopping as you approach an intersection, and proceed with due caution. Consider using a different siren tone as you approach an intersection. Remember, the siren is a request that other drivers yield the right-of-way to you; it does not guarantee they will.

Driver Anticipation

Never assume that motorists and pedestrians will yield the right-of-way or that other drivers will respond predictably when they encounter an emergency vehicle. Always assume that people cannot hear the siren and/or public address (PA) system or see the ambulance until proven otherwise by their actions. Motorists may indeed pull over to the nearest curb and stop or drive as close to the curb as possible, but you cannot take this behavior for granted. Operate the ambulance in a manner that allows you adequate time and space to safely maneuver around vehicles that may have suddenly stopped or pulled over in the wrong direction. At any time, a motorist might stop suddenly in front of the ambulance or pull in front of you. These actions may result in a collision. Whenever a motorist yields the right-of-way to you, attempt to establish eye contact with the person to confirm you have been seen.

Safety

When multiple agencies respond to the same emergency, responders may choose the same route of travel. In such instances, be extremely cautious at intersections and side streets. Aside from the fact that personal vehicles are now virtually soundproof, a motorist may be distracted by the first emergency vehicle and may not see another vehicle coming behind the first. If you must travel behind a fire truck or law enforcement vehicle, then make sure you leave plenty of distance between your vehicles and use a different siren tone.

It is often difficult for motorists to hear instructions called out over the PA system, especially when their windows are closed and their radios are loud. The acoustic glass and increased insulation in many modern vehicles provide a quieter environment for motorists but decrease their ability to hear noises from outside of the vehicle, such as emergency sirens or instructions called out over the ambulance's PA system. The PA system may make the situation worse because motorists may hesitate or make unexpected moves so that they can hear or follow instructions. Moreover, when you issue commands to motorists and pedestrians over the PA system,

they are now distracted from the business of driving. With this said, you should not use the PA system often, if at all, while you drive the ambulance.

Sirens, too, may be difficult for motorists to hear in modern vehicles. Effective siren distances are much shorter than you would think. Keep in mind that as you increase the speed of your ambulance, you decrease the amount of time and space that vehicles in front of you have to hear your siren and react appropriately. Some ambulances are equipped with a specialized siren (eg, the Rumbler) that emits low-frequency siren sound waves that produce a vibration and may penetrate vehicles better than traditional sirens, allowing motorists to feel the siren.

Most important, always drive defensively. Never assume what another motorist will do unless you get a clear visual signal. Even then, be prepared to take defensive action in the case of a misunderstanding, panic, or careless driving on the part of the other motorist. Aggressive ambulance driving such as cutting off other vehicles may also cause anxiety or irrational behavior in other motorists, because you may not allow enough time for them to respond to your vehicle.

The Cushion of Safety

To operate an ambulance safely, maintain a safe following distance from the vehicles in front of you and try to avoid being tailgated from behind. Also ensure that the **blind spots** in your mirrors do not prevent you from seeing vehicles or pedestrians on either side of the ambulance. When you follow these steps, you are maintaining a **cushion of safety**. To ensure that you have enough reaction time and stopping distance from the vehicle in front of you, follow at a safe distance, allowing the motorist enough time to move over to the right. If the motorist does not move, then you need to allow for enough time to avoid colliding with the vehicle. This means driving approximately 4 seconds behind a vehicle traveling at an average speed (remember the 4-second rule).

While operating in emergency mode, tailgaters may follow your vehicle dangerously closely in congested areas simply to use your ambulance to get through traffic. If you stop the ambulance suddenly, then the tailgating vehicle could collide with the rear of the ambulance, possibly causing you to lose control and strike other vehicles or pedestrians.

Always scan your rearview and side mirrors for vehicles that are following too closely.

If you are being tailgated, then never speed up to create more distance. The tailgater may, in turn, increase their speed to continue to follow you through traffic, thereby decreasing your cushion of safety and reaction time. Slamming on your brakes to scare the other motorist usually does not work either and may cause a collision. You can have your dispatcher contact the local police to let them know that someone is driving recklessly behind you.

Never, under any circumstance, get out of the ambulance to confront a driver. This action will only delay your response to the scene or transport of the patient and can lead to a dangerous situation. It is also unprofessional for you to become involved in a verbal argument with any member of the public and may lead to disciplinary actions or termination, depending on the conduct regulations of your service.

Finally, be aware that, even with well-positioned mirrors, there are three blind spots around the ambulance that you cannot see with the side or rear-view mirrors:

1. The rearview mirror itself creates a blind spot, obstructing the view ahead and preventing you from seeing pedestrians or vehicles. To eliminate this blind spot, lean forward in your seat so that the mirror does not obstruct the view, especially when making turns at intersections.
2. You cannot fully see the rear of the vehicle through the rearview mirror; therefore, it is a blind spot. Because of the configuration of modern ambulances and the relative height of the vehicle, the rearview mirror generally gives you only a view of the patient compartment at best and is not intended to be used for alerting the driver of a vehicle behind the ambulance. Because of this blind spot, many crashes occur when the ambulance is backing up. It is highly recommended, and required in many jurisdictions, that you use a **spotter** to help you back up the ambulance (discussed later in this chapter). Rear-facing cameras are also helpful and much more common; however, cameras do not replace the assistance of a spotter if one is available.
3. Often you cannot see the side of the ambulance through the side-view mirrors at a certain angle. You may be unable to see an entire

vehicle in the side mirrors, even though the vehicle is right next to the ambulance. To eliminate this problem, many EMS agencies place small, rounded mirrors on the side mirrors to assist you in visualizing this blind spot. However, if these mirrors are unavailable, then you need to lean forward or backward in the seat to eliminate the blind spot. This technique is especially important to use when shifting lanes or making turns. If you are making a turn from an appropriate lane or across multiple lanes, be aware that other motorists, bicyclists, or pedestrians may have traveled alongside the ambulance as you are beginning your turn.

Safety

Ambulance crashes that kill EMS providers, patients, or occupants of other vehicles are disturbingly common. Many of them could be prevented by the driver of the ambulance. Attending thoroughly to your own driving skills, driving according to established standards, and dealing with any obvious deficiencies in your partner's driving skills are all crucial to your safety on the job.

Frequently scan your mirrors for any new hazards to maintain your cushion of safety; however, keep in mind that your mirrors can give you a misleading view and may block pedestrians or vehicles. Adjust your position in the driver's seat to avoid blind spots in your mirrors. Always use a spotter whom you can see from the driver's side mirror.

Emergency Vehicle Control

As the driver of an ambulance, you have only two ways to control the vehicle: by changing its direction or changing its speed. Either maneuver requires a continuous rolling contact between the surface of the tires and the surface of the road. Two factors are involved in this contact. The first is the **coefficient of friction**, which is a measure of the grip of the tires on the road; **friction** is resistance to the motion of one body against another. The second factor is the **footprint** of the tire, or the area of contact between the tire and surface of the road. On the typical ambulance, the footprint is about 8 inches (20 cm) long and as wide as the tire.

The grip of the tire on the road may vary widely on different parts of the same road, depending on the condition of the surface, the age of the road, and the weather. Unpaved roadways may also present a challenge, especially in inclement weather. The grip of the tire also varies according to its tread design and wear. As a driver, you must constantly evaluate the road surface. Ask yourself: At a given speed, how much frictional force can the tires apply before the ambulance becomes unstable? This evaluation is especially important while cornering, in which additional centrifugal force is acting on the vehicle.

Words of Wisdom

Centrifugal force is the tendency for objects to be pulled outward when rotating around a center. Vehicles are subject to this force when making a turn. If you must brake on a turn, then brake gently while making the turn.

Vehicle Size and Distance Judgment

The length and width of the ambulance are critical factors in maneuvering, driving, and parking it. These factors are especially important with type I and type III ambulances, which are wider than they look from behind the steering wheel. To brake and pass effectively, you must know the width and length of your vehicle. As mentioned previously, crashes often occur when the driver is backing up the ambulance. To avoid any incidents, always use a spotter outside the ambulance as a guide when you are backing up. The size and weight of the ambulance also greatly influence braking and stopping distances. Good peripheral vision and depth perception will help you to judge distances, but they are no substitute for intensive training, experience, and frequent evaluation of the vehicle.

Road Positioning and Cornering

Road position means the position of the vehicle on the roadway relative to the inside or outside edge of the paved surface. To corner efficiently, you must know the present position of the ambulance and its projected path. The aim is to take the corner at the speed that will put you in the proper road position as you exit the curve (**FIGURE 39-22**). The apex of the turn through a curve is the point at which the

FIGURE 39-22 To keep the ambulance in the proper lane on a curve, you must know the present position and projected path of the vehicle, and take the corner at the correct speed.

© Jones & Bartlett Learning.

ambulance is no longer driving into the corner, but is beginning to drive out of it. If you reach the apex early in the curve, then the ambulance will be forced toward the outside of the roadway as it exits the curve. If you reach the apex late in the curve, then the ambulance will tend to stay on the inside of the roadway; this tactic helps you to keep the ambulance in the proper lane and allows room for error if you enter the turn too fast.

Words of Wisdom

Hold the steering wheel with your left hand at the 9-o'clock position and your right at the 3-o'clock position. This technique allows you to turn the wheel without removing either hand; one hand pulls while the other slides so that they remain parallel. Your hands should not pass the 12-o'clock or 6-o'clock positions. Let the hand that was pulling start to slide, and use the opposite hand to pull, which will keep both hands on the steering wheel at all times.

Controlled Acceleration and Braking

Recall that the chassis is the structural framework of a vehicle. The **chassis set** is the transfer of weight (center of mass) to different points on the chassis. Basically, the weight of a vehicle is concentrated over one of three points on the chassis: (1) the

front wheels, (2) the rear wheels, or (3) the center between the front and rear wheels. The transfer of weight from one point to another is caused by either acceleration or deceleration. When a vehicle accelerates, the weight is transferred to the rear. As a result, the front wheels have some loss of traction, which means that your ability to steer is reduced. A vehicle has a tendency to travel in a straight line. When braking, the opposite shift in weight occurs; this factor is why the rear end of the vehicle tends to slide to the outside of a curve when cornering.

Controlled Acceleration

Controlled acceleration is the use of acceleration to control the vehicle. Acceleration is most efficient when the vehicle is traveling in a straight line, because the force of linear acceleration is equally distributed to the rear wheels. If you accelerate in a curve or during a turn, however, then you force the vehicle to the outside of the curve. If acceleration in this direction becomes excessive, then the vehicle may drift out of control and become unstable. Therefore, accelerate as you come out of a curve to provide stability to the vehicle.

Words of Wisdom

Take your foot off the accelerator when you enter a curve, allowing the ambulance to coast into it, and accelerate as you exit the curve to provide the greatest stability to the vehicle.

Controlled Braking

Controlled braking is the use of the brakes to control the vehicle. Brakes not only control the movement of the vehicle, causing it to slow or stop, but they also help to control its direction. The safest, most efficient method of braking is to brake while the vehicle is traveling in a straight line. Braking during a turn causes a loss of efficiency. You might not notice this effect at low speed, but it becomes more apparent at higher speeds. Applying the brakes while cornering is not an effective way to slow the vehicle and may actually cause it to skid or spin.

Each vehicle has a different braking action. With experience and practice, you will develop a sense of the proper brake pressure. For example, the brakes on types I and III ambulances have a heavier feel

than the brakes on a type II ambulance. Braking on a diesel-powered unit will be different from braking on a gasoline-powered unit, even if the two units are identically equipped. Certain heavy vehicles use air brakes, which have yet another feel. Get to know each vehicle you drive, and be sure you understand its braking characteristics and the appropriate downshifting techniques.

Backing Up the Ambulance

Backing up a vehicle is the most common source of vehicle damage and may result in costly repairs. Most EMS agencies have established a policy regarding this process. If possible, avoid situations in which the ambulance will have to be backed up. If it must be done, then remember to follow these rules:

- Use a spotter to guide you.
- Agree on hand signals to use with the spotter before you place the ambulance in reverse. Some people have different ideas of which gesture means “Stop.”
- Keep your spotter in view at all times. If you lose sight of the spotter, then immediately stop until the person is back in your line of sight.
- Keep your window rolled down when in motion. This practice may allow you to hear people warning you of unseen dangers.
- Walk around the ambulance before getting behind the wheel and look up as well as down. Objects on the ground may not be visible after you start backing up.
- Use audible warning devices whenever the ambulance is in motion.

Weather and Road Conditions

Although most ambulance crashes occur on clear days with dry roads, certain conditions can limit your ability to control your vehicle. Remember, ambulances do not handle the same as personal vehicles. Ambulances are heavier than most vehicles and will have a longer braking time and stopping distance. In addition, the weight of the ambulance is unevenly distributed, which makes it more prone to rollover. These differences, in addition to adverse environmental conditions, greatly increase the chance that a crash may occur. Therefore, be constantly alert to changing weather and road conditions. Whether traveling to or coming from an

emergency, modify your speed according to road conditions. Take warnings of ice or hazardous conditions seriously, and be prepared to take an alternative route, if necessary. During a major disaster, all public safety and emergency services should be coordinated. If you encounter unexpected traffic congestion, then notify the dispatcher so other emergency vehicles can select alternative routes.

Even the most careful drivers will occasionally encounter unexpected situations that may require special driving skills. However, if you drive at a speed that is appropriate for the weather and road conditions and maintain an adequate cushion of safety, then you will minimize these situations. Therefore, it is safer if you decrease speed in weather situations involving fog, rain, snow, or ice. The following are examples of adverse conditions that require you to decrease speed, increase following distance, and be alert.

Hydroplaning

On a wet road, a tire usually displaces the water on the road surface and stays in direct contact with the road. However, at speeds of greater than 30 miles per hour (mph), tires may be lifted off the road as water builds up underneath; the vehicle may then feel as if it is floating. This condition is known as **hydroplaning**. At higher speeds on wet roadways, the front wheels may actually be riding on a sheet of water, robbing the driver of control of the vehicle. If hydroplaning occurs, then gradually slow down without slamming on the brakes.

Water on the Roadway

Wet brakes will not slow the vehicle as efficiently as dry brakes will, and the vehicle may pull to one side or the other. If at all possible, avoid driving through large pools of standing water; often, you cannot tell how deep they are. If you must drive through standing water, then slow down and turn on the windshield wipers. After driving out of the water, lightly tap the brakes several times until they are dry. If the vehicle is equipped with antilock brakes, then apply a steady, light pressure to dry the brakes. Avoid driving through moving water at all times.

Decreased Visibility

The presence of fog, smog, snow, or heavy rain indicates that you must slow down. Warn the vehicles

behind you by turning on your emergency warning lights. At night, use only low headlight beams for maximum visibility without reflection. Always use headlights during the day to increase your visibility to other drivers. Also, watch carefully for stopped or slow-moving vehicles.

Ice and Slippery Surfaces

A light mist on an oily, dusty road can be just as slippery as a patch of ice. Good all-weather tires and an appropriate speed will significantly reduce traction problems. If you are in an area that often has snowy or icy conditions, then consider using studded snow tires or tire chains, if they are permitted by law. Be especially careful on bridges and overpasses when temperatures are close to freezing. These road surfaces will freeze much faster than surrounding road surfaces because they lack the warming effect of the ground underneath.

Words of Wisdom

Although preventing skids and sliding is ideal, you are likely to skid or slide occasionally, especially if you live in climates with ice and snow. Your training should include the technique for correcting slides during turns. If you are likely to drive on ice and snow, then practice control maneuvers until they become automatic. Practice at low speeds in open areas with no danger of collisions. Remember that four-wheel-drive and front-wheel-drive vehicles function differently than rear-wheel-drive vehicles when sliding. It is also important to remember that although four-wheel-drive vehicles have better traction for acceleration in slippery conditions, they do not stop any faster than two-wheel-drive vehicles do.

Fatigue

Fatigue has many causes, such as stress, working the night shift, and lack of quality sleep in accordance with your body's circadian rhythms. As a result of fatigue, operating a large vehicle, such as an ambulance, creates a considerable risk. You must be able to recognize when you are fatigued. Do not be ashamed to admit it to yourself, your partner, or your supervisor. If you are feeling fatigued, then you should be placed out of service for the remainder of the shift or until the fatigue has passed and you feel capable of operating the vehicle safely.

Safety

If possible, avoid these distractions while driving:

- Mobile data terminals
- GPS devices
- Mobile two-way radios
- Mobile phones
- Visual and audible devices (emergency warning lights and siren)
- Vehicle stereo
- Wireless devices
- Eating and/or drinking

Laws and Regulations

Regulations regarding vehicle operations vary among states and by city, but some regulations are the same regardless of location. Drivers of emergency vehicles have certain limited privileges in every state. However, these privileges do not lessen their liability in a crash. In fact, in most cases, the driver is presumed to be guilty if a crash occurs while the ambulance is operating with emergency warning lights and siren. Motor vehicle crashes comprise a large number of lawsuits against EMS personnel and systems.

While on an emergency call, emergency vehicles typically are exempt from usual vehicle operations. If you are on an emergency call and are using your emergency warning lights and siren, then you may be allowed to take the following actions:

- Park or stand in an otherwise illegal location
- Proceed through a red traffic light or stop sign after stopping at the intersection
- Drive faster than the posted speed limit
- Drive against the flow of traffic on a one-way street or make a turn that is normally illegal
- Travel left of center to make an otherwise illegal pass

Remember, these exemptions vary by state and local jurisdiction. Check your local statutes for regulations in your area.

An emergency vehicle is never allowed to pass a school bus that has stopped to load or unload children and is displaying its flashing red lights or stop signal arm. If you approach a school bus that has its lights flashing, then stop before reaching the bus and turn off your siren. Next, wait for the

bus driver to make sure the children are safe, close the bus door, and turn off the flashing lights. Only then may you carefully proceed past the stopped school bus.

Special Populations

When you approach a school bus that is stopped with its stop sign out, stop and turn off your siren. Wait until the bus driver turns off the flashing lights and disengages the stop signal arm before cautiously proceeding. Children are unpredictable and may run into your path of travel when scared or confused by the siren. Once the bus driver has turned off the stop sign, indicating all children are safely out of the way, proceed carefully past the site, paying particular attention to all children in the area.

Right-of-Way Privileges

A right-of-way privilege is just that: a privilege. State motor vehicle statutes or codes often grant the operator of an emergency vehicle the right to disregard the rules of the road when responding to an emergency. However, in doing so, the operator of an emergency vehicle must not endanger people or property under any circumstances.

Consider this case: An ambulance is approaching an intersection that is controlled by a four-way stop sign. The ambulance, with its emergency warning lights and siren turned on, proceeds through the intersection without slowing or stopping and collides with a vehicle coming from its right. Did the operator of the ambulance act appropriately by going through the intersection in this manner?

Right-of-way privileges for ambulances vary from state to state. Some states allow you to proceed through a red light or stop sign after you stop and make sure it is safe to continue. Other states allow you to proceed through a controlled intersection with so-called due regard, using flashing lights and siren. Due regard means that you may proceed only if you consider the safety of all people who are using the highway. If you fail to use due regard, then your service might be sued. If you are found to be at fault, then you may personally have to pay punitive damages or face civil and/or criminal sanctions.

Learn your local right-of-way privileges. Exercise them only when it is absolutely necessary for the patient's well-being. The use of emergency

Safety

Always pass on the left, even if it means traveling into oncoming traffic. This action should only be done when you are driving in emergency mode with emergency warning lights and siren activated.

warning lights and siren is a matter of state and local practice and protocol.

Use of Escorts

Using a police escort is an extremely dangerous practice. As discussed previously, when other motorists hear a siren and see a police vehicle passing, they might assume that the police vehicle is the only emergency vehicle and might not expect the ambulance. The only time an escort is justified is when you are in unfamiliar territory and truly need a guide. In such cases, alert motorists that a second unit is approaching by using a siren tone that is different from the police vehicle. Be prepared to stop if needed. If you are being guided, then follow at a safe distance. Do not assume nearby traffic will be aware of your presence. Exercise extreme caution when following another emergency vehicle, particularly when approaching an intersection.

Intersection Hazards

Intersection crashes are the most common and usually the most serious type of crash in which ambulances are involved. Always be alert and careful when approaching an intersection. If you are on an urgent call and cannot wait for the traffic light to change, then come to a momentary stop at the traffic light and look around for other motorists and pedestrians before proceeding into the intersection. Scan the intersection and your mirrors for hazards and clear each lane before you proceed. Direct your full attention to the road while proceeding through the intersection; this is not the time to talk on the radio or consult the automatic vehicle location (AVL) map.

Motorists who “time the traffic lights” present a serious hazard. You may arrive at an intersection while the light is green. At the same time, a motorist who is timing the lights on the cross street arrives at the intersection. The motorist has a red light but knows that it is about to turn green and is expecting

to go through. The stage is now set for a serious collision.

Another common intersection hazard occurs when multiple emergency vehicles are responding through the same intersection. Having “convoys” of emergency vehicles is not uncommon as multiple resources respond from a similar location. A motorist who has yielded the right-of-way to the first vehicle may proceed into the intersection without expecting a second vehicle. You should exercise extreme caution in these situations. To signal motorists that a second unit is approaching, use a siren tone that is different from that of the first vehicle.

You must also be aware that additional emergency vehicles responding to the same call, or responding to a different emergency call, may be coming through the same intersection from a different direction. Serious accidents could occur when two emergency vehicles enter the same intersection unless both of the drivers are operating with due regard, allowing them the time to recognize the other vehicle responding and safely proceed through the intersection.

Highways

When you are responding to an emergency call and you must travel on the highway, shut down your emergency warning lights and siren until you have reached the far left lane. Shutting down your emergency warning devices minimizes the possibility of confusion for motorists who might not know what to do or where to go. Remember to travel in the far left lane whenever possible, which allows the ambulance to safely pass vehicles while still leaving a cushion of safety on the left side of the ambulance in case of emergency or unexpected obstacles.

When you exit the highway, follow the same procedures as when you entered the highway: turn off all emergency devices, move onto the off-ramp, and then reactivate the emergency warning lights and siren if necessary.

Unpaved Roadways

When you are required to drive the ambulance on an unpaved roadway, you must take special care. Unpaved roadways often have uneven surfaces, as well as large potholes. While responding on this type of roadway, operate the vehicle at a lower speed and maintain a firm grip on the steering wheel in an

effort to maintain complete control of the ambulance at all times. During the transport phase, these practices will help to provide a smoother ride for the AEMT and patient on the stretcher.

School Zones

When you respond through a school zone with your emergency warning lights turned on, it is important to remember that the lights and siren tend to attract children to the roadway and create a potential hazard. In many states, it is unlawful for an emergency vehicle to exceed the speed limit in school zones regardless of the patient's condition.

Air Medical Operations

Air ambulances are used to evacuate medical and trauma patients. They land at or near the scene and transport patients to trauma facilities every day in many areas. They may also be used for search and rescue operations.

The two basic types of air medical units are fixed-wing aircraft and rotary-wing aircraft,

otherwise known as helicopters (**FIGURE 39-23**). Fixed-wing aircraft are generally used for interhospital patient transfers over distances greater than 100 to 150 miles (161 to 241 km). For shorter distances, ground transport or rotary-wing aircraft are more efficient.

Specially trained medical flight crews accompany all air ambulance flights. This section will focus on the rotary-wing aircraft. Your role in fixed-wing aircraft transfers will probably be limited to providing ground transport for the patient and medical flight crew between the hospital and the airport.

Rotary-wing aircraft have become an important tool in providing emergency medical care. The survival rates in trauma patients are directly related to the time that elapses between injury and definitive treatment. Most helicopters that are used for emergency medical operations fly well in excess of 100 mph in a straight line, without road or traffic hazards. The crew may include flight paramedics, flight nurses, specialty providers such as respiratory therapists, and/or physicians. Air medical transport, especially the use of helicopters, has done much to

YOU are the Provider

Part 4

After the helicopter has safely landed, you are met by the flight crew. You recently completed an orientation course for the local flight service, and you know it likes to have the patient packaged completely prior to its arrival. You proceed to give an extensive report of your findings. After the flight crew has examined the patient, they elect to secure the airway with an endotracheal tube with the assistance of medications to temporarily sedate and paralyze the patient. After they have confirmed tube placement by both physical exam and capnography, you accompany them to the helicopter with the patient on the stretcher. As you approach the rotor arc, a flight crew member escorts you to the side of the helicopter and you quickly load the patient in. When you have completed loading the patient, a flight crew member escorts you back out of the rotor arc, and you proceed back to your ambulance to perform a quick decontamination of the unit. Shortly thereafter, the helicopter lifts off and proceeds to the burn center.

Recording Time: 14 Minutes

Respirations	6 breaths/min (unassisted)
Pulse	130 beats/min; thready
Skin	Burns to face, chest, and arms
Blood pressure	90/50 mm Hg
Oxygen saturation (SpO₂)	95% on 100% oxygen via bag-mask device
Pupils	Equal but sluggish to respond

9. What is the most important rule when working around helicopters on an emergency scene?
10. Who has ultimate control of the aircraft when on an emergency scene?

**A****B**

FIGURE 39-23 **A.** Fixed-wing aircraft are generally used to transfer patients from one hospital to another over distances greater than 100 to 150 miles (161 to 241 km). **B.** A rotary-wing aircraft, or helicopter, is used to help provide emergency medical care to patients who need to be transported quickly over shorter distances.

speed up the transfer of patients from the trauma scene to definitive care. This mode of transport presents certain risks, however, and it is only appropriate in certain circumstances. You must consider several factors before calling for an air ambulance. Does the patient's condition warrant the risk of using air medical transport? Will use of the air ambulance save the patient time in getting to definitive care once all other factors are considered?

Advantages of Using Air Ambulances

Air ambulances have an advantage over ground transport in that they reduce transport time and may help the patient receive definitive treatment

within the Golden Hour (sometimes called the Golden Period). The decision to use rotary-wing transport should be made as early in the call as possible. If, after the patient assessment, it is determined that the helicopter is not needed, then it can always be returned to service. Some districts have local protocols that permit the automatic dispatch of a helicopter.

You need to weigh several factors to determine whether ordering a helicopter is appropriate. First, consider the time needed to start the engine of the aircraft, load personnel and gear, and travel to the scene (sometimes located a great distance away). After the helicopter arrives at the scene, time must be allotted to land the aircraft, transfer the patient to the flight crew, package the patient for air transport, and load the patient into the helicopter. Especially in metropolitan areas, it can be difficult to justify use of the helicopter. Severe traffic congestion or prolonged extrication times may sometimes make the use of a helicopter appropriate in urban areas. However, the use of an air ambulance is warranted if the transport time to the hospital by ground ambulance is too long considering the patient's condition. Use of an air ambulance may be warranted if the patient has a spinal injury and the terrain over which the patient must be carried is very rough. Even though the patient is stabilized, ground transport in a vehicle that is bouncing on the road could further injure the patient. As the AEMT on scene, you are the best judge of the patient's transportation needs. **TABLE 39-7** summarizes the advantages and disadvantages of using an air ambulance.

Disadvantages of Using Air Ambulances

The disadvantages of an air ambulance include interior space limitations, altitude limitations, weight limits for passenger load, and high cost. Patients in cardiac arrest or those who appear to be in precordial arrest should be transported by ground ambulance. It is difficult to treat a patient in cardiac arrest in the helicopter because of the small cabin size.

In addition, air ambulances are usually restricted to flying under certain visual flight rules, so anything that interferes with visibility, such as adverse weather conditions, can make it too dangerous to fly. The terrain, such as uneven ground and

TABLE 39-7 Advantages and Disadvantages of Using Rotary-Wing Aircraft (Helicopter)

Advantages of Using an Air Ambulance	Disadvantages of Using an Air Ambulance
Availability of specialized skills or equipment	Weather conditions may prohibit use or limit speed of travel
Possibility of rapid transport (typically between 130 and 150 mph)	Altitude limitations may prohibit use
Possibility of access to remote areas	Aircraft cabin size
Availability of helicopter hospital helipads	Terrain may prohibit use
	High cost of operation
	Patient's condition (certain conditions may not be able to be treated within the confines of a helicopter; also, certain conditions may be worsened by altitude change)

loose objects such as rocks or debris, may also make it difficult to land the helicopter safely.

Medical Evacuation Operations

A medical evacuation is commonly known as a **medevac** and is generally performed exclusively by helicopters. Most rural and suburban EMS jurisdictions and many urban systems have the capability to perform helicopter medevacs or have a mutual aid agreement with another agency, such as a police or hospital-based medevac service, to provide such service. Familiarize yourself with the medevac capabilities, protocols, and procedures of your particular EMS agency. Consider the following general guidelines before initiating a medevac operation.

Calling for a Medevac

Every agency has specific criteria for the type of patient who may receive medevac and how and

when to call for a medevac. You must be familiar with the particular criteria used in your agency. These basic guidelines will help you to understand the process better.

- **Why call for a medevac?** The transport time to the hospital by ground ambulance is too long considering the patient's condition. Road, traffic, or environmental conditions limit or completely prohibit the use of a ground ambulance. The patient requires advanced emergency medical care that you are unable to provide. The presence of multiple patients will overwhelm resources at the hospital reachable by ground transport. (In this case, the helicopter may respond directly to the scene or it may be called to the hospital to transfer a patient to another facility with the capacity to provide definitive care.)
- **Who receives a medevac?** Patients with time-dependent injuries or illnesses may require a medevac. They are widely used for patients suspected of having a stroke, heart attack, or serious spinal cord injury, such as injuries sustained in a motor vehicle crash or while diving into a pool or horseback riding. Serious conditions that may require the use of helicopter medevacs may be found in remote areas and involve scuba diving accidents, near drownings, or skiing and wilderness accidents. Other patients who may warrant the use of medevac are trauma patients and candidates for limb replantation (for amputations), a burn center, a hyperbaric chamber, or a venomous bite center.
- **Whom do you call?** Generally your dispatcher must be notified first. In some regions, after the medevac has been initiated, the ground EMS crew may be able to communicate with the flight crew on a specially designated radio frequency. If available, then it is important to keep this frequency clear of chatter and lengthy communications. You may be asked to give a brief presentation or update on the patient's condition. In this case, gather your thoughts and speak clearly and concisely, avoiding information that is not pertinent. Another important topic of communication between the ground and flight EMS crews will be where to land the helicopter. This topic will be covered later in this chapter.

Medevac Issues

As discussed, you must consider several important factors while making the decision to request medevac. These factors include weather, environment or terrain, altitude, airspeed limitations, cabin size, and cost. Typically, helicopters are unable to operate in severe weather such as thunderstorms, blizzards, and heavy rain. The environment may pose a risk as well. In mountainous or desert terrain, too many hazards may be present in the immediate vicinity to safely land the helicopter in the desired location.

As the elevation increases, the air thins, making it more difficult for pilots and patients to breathe. Because of this danger, helicopters have a maximum limit on flight elevations. Most helicopter services are limited to flying at 10,000 feet above sea level. This limitation could create a problem if your patient is located at 13,500 feet above sea level. It is important to remember that medevac helicopters are not jets, and it takes time for them to arrive on the scene, because of limitations in airspeed.

Because of the confined space of the helicopter cabin, helicopters are limited in the number of patients that can be safely transported and by the size of the patient that they can safely transport. Although a helicopter may be able to lift off with a 500-pound (227-kg) patient, it may be impossible to safely fit and secure these patients into the cabin area because of their size and girth. Newer helicopters can fit and lift bigger patients. Know what is available in your area.

Typical medevac flights are much more expensive than ground transport by ambulance. However, the level of care may be higher and the overall transport time may be shorter in the helicopter. Do not base the decision to request a medevac on the perceived ability of the patient to pay the medical bill, but rather on the medical necessity.

Establishing a Landing Zone

Although a helicopter can fly straight up and down, such movement is the most dangerous mode of operation. The safest and most effective way to land and take off is similar to that used by fixed-wing aircraft. Landing at a slight angle allows for safer operations. Takeoff combines a gradual lift and forward motion to travel up and out on a slight angle.

An important part of conducting a medevac is choosing the best location. Establishing a landing zone is the responsibility of the ground EMS crew. This process involves more than simply looking for a clear space. Be prepared to take action to make certain that the flight crew is able to land and take off safely. Actions to take and considerations to include when selecting and establishing a landing zone include the following:

- Ensure the area is a hard or grassy level surface that ideally measures 100×100 feet (30×30 m) and no less than 60×60 feet (18×18 m). If the landing zone is not level, then notify the flight crew of the steepness and direction of the slope.
- Ensure the area is clear of any loose debris that could become airborne and strike the helicopter or the patient and flight crew. Loose debris includes branches, trash bins, flares, caution tape, and medical equipment and supplies.
- Examine the immediate area for any overhead hazards such as power lines or telephone cables, antennas, and tall or leaning trees. Immediately relay the presence of these hazards to the flight crew because an alternative landing zone may be required. The flight crew may request that the hazard be marked or illuminated by weighted cones or that an emergency vehicle with its lights turned on be positioned next to or under the potential hazard.
- To mark the landing zone, use weighted cones or position emergency vehicles at the corners of the landing zone with headlights facing inward to form an X on the ground. This procedure is essential during night landings. Never use caution tape to mark the site. The use of flares is also not recommended, because not only can they become airborne, but they also have the potential to start a fire or cause an explosion.
- Move all nonessential people and vehicles a safe distance outside of the landing zone.
- Both the approach and the departure will be performed into the wind. If the wind is strong, then radio to the flight crew the direction of the wind. The flight crew may request that you improvise some form of wind directional device to aid the crew's approach.

Words of Wisdom

Consider working with local helicopter agencies to establish predesignated landing zones. Requesting a helicopter for an emergency medevac can be much less stressful if your service has already identified several places that are suitable for a helicopter landing zone.

Landing Zone Safety and Patient Transfer

Be familiar with the capabilities, protocols, and methods for accessing helicopters in your area. Helicopter services provide training for AEMTs in ground operations and safety. Interactions with flight personnel should be comprehensive. Patients should be packaged prior to arrival of the air ambulance and an extensive report given to the flight crew for transfer of care. The following discussion is an introduction to safe medevac operations and is not intended to be substituted for the more extensive courses available locally.

Helicopter safety is not complicated. Your personal safety depends on knowing some basics about helicopter operation and exercising common sense and constant awareness. The types of helicopters that are used for medical operations vary, but the dangers are the same. If you are familiar with the way helicopters work and follow the pilot's instructions, then you will minimize these dangers. Be sure to do nothing near the helicopter and go only where the pilot or flight crew directs you.

The most important rule is to keep a safe distance from the aircraft whenever it is on the ground and "hot," which means when the main and tail rotors are spinning. The rotor blades will usually remain spinning because the flight crew does not generally expect to remain on the ground for a long time. This means that you should stay outside the perimeter of the landing zone unless directed by the pilot or a member of the flight crew to come to the aircraft. Usually, the flight crew will come to you carrying the crew's own equipment and will not require any assistance inside the landing zone. If you are asked to enter the landing zone, then stay away from the tail rotor; the tips of its blades move so rapidly that they appear invisible. With the

FIGURE 39-24 Approach a helicopter between the 10-o'clock and 2-o'clock positions as the pilot faces forward.

© Jones & Bartlett Learning.

possible exception of a rear-loading aircraft, always approach a helicopter from the front, even if it is not running, and approach only after the pilot signals it is clear to do so. If you must move from one side of the helicopter to another, then go around the front. Never duck under the body, the tail boom, or the rear section of the helicopter; the pilot cannot see you in these areas. The proper approach area is between the 10-o'clock and 2-o'clock positions as the pilot faces forward **FIGURE 39-24**.

Another area of concern is the height of the main rotor blade. On many aircraft, it is flexible and may dip as low as 4 feet (1 m) off the ground (**FIGURE 39-25**). When you approach the aircraft, walk in a crouched position. If the helicopter is on a gradient, approach from downhill. Wind gusts can alter the blade height without warning, so protect your equipment as you carry it under the blades. Air turbulence created by the rotor blades can blow off hats and loose equipment. These objects, in turn, can become a danger to the aircraft and personnel in the area.

When you accompany a flight crew member, follow directions exactly. Never try to open any aircraft door or move equipment unless instructed by a flight crew member. When told to approach the

aircraft, use extreme caution and pay constant attention to hazards.

Keep the following guidelines in mind when operating at a landing zone:

- Familiarize yourself with the helicopter hand signals used within your jurisdiction (**FIGURE 39-26**).
- Do not approach the helicopter unless instructed and accompanied by the flight crew.
- Ensure all patient care equipment, including oxygen tanks, cervical collars, and head immobilizers, is properly secured to the stretcher

FIGURE 39-25 The main rotor blade of the helicopter is flexible and may dip as low as 4 feet (1 m) off the ground.

© Jones & Bartlett Learning.

and that the patient is fastened as well. Any loose articles or belongings such as hats, coats, or bags that belong to the patient or flight crew should not be brought into the landing zone and will likely need to be transported to the hospital by ground.

- Be aware some helicopters may load patients from the side, whereas others have rear-loading doors. Regardless of where the patient is being loaded, always approach the aircraft from the front unless otherwise instructed by the flight crew. It is very important that the pilot be able to see anyone who comes under the rotors. Always take the same path when exiting away from the helicopter, moving the patient headfirst.
- Smoking, open flames, and flares are prohibited within 50 feet (15 m) of the aircraft at all times.
- Wear eye protection during approach and takeoff.

Safety

Pay close attention to directions by the flight crew when approaching the aircraft.

FIGURE 39-26 Some examples of helicopter hand signals. Be familiar with those used within your jurisdiction.

© Jones & Bartlett Learning.

Communicating With Other Agencies

When you interact with other agencies, communication issues are always a possibility. Medevacs are no exception. Whereas the typical EMS system has its specific and well-defined jurisdiction, medevacs respond to service requests throughout a large, multijurisdictional area. Because of this large area with numerous jurisdictions, the medevac interacts with many services on a multitude of different radio frequencies.

To prevent any miscommunication, when the request is made for a medevac response, the request should include a ground contact radio channel (typically a preestablished mutual aid channel), as well as a call sign of the unit that the medevac should make contact with.

Special Considerations

Night Landings

Nighttime operations are considerably more hazardous than daytime operations because of the darkness. Remember that what is easy for you to see from the ground may not be visible at all from the aircraft. The pilot will generally fly over the area at least twice at varying altitudes with the lights of the helicopter turned on to identify potential obstacles and overhead wires, which can be hard to see. Medevac pilots and flight crew members use night-vision goggles during nighttime landing zone operations. Do not shine spotlights, flashlights, or any other lights in the air to help the pilot; they may temporarily blind the pilot. Instead, direct low-intensity headlights or lanterns toward the ground at the landing site from opposite corners to form an X

Safety

at the center of the landing zone. Turn off all headlights or lanterns that are facing in the direction of the aircraft after it has landed. After the helicopter has landed, do not aim lights near the aircraft. Always make certain the flight crew is aware of any overhead hazards or obstructions, and illuminate these if possible.

Landing on Uneven Ground

If the helicopter must land on a grade, then extra caution is advised. The main rotor blade will be closer to the ground on the uphill side. In this situation, approach the aircraft only from the downhill side or as directed by the flight crew (**FIGURE 39-27**). Do not move the patient to the helicopter until the flight crew has signaled that the crew is ready to receive you. A flight crew member will direct and assist you in loading the patient.

Medevacs at Hazmat Incidents

Immediately notify the flight crew of the presence of hazmat at the scene. The helicopter generates tremendous wind and may easily spread any hazmat vapors present. Always consult the flight crew and incident commander about the best approach and distance from the scene for a medevac. The landing zone should be established upwind and uphill from the hazmat scene. Any patients who have been exposed to a hazmat must be properly decontaminated before they can be loaded into the aircraft.

FIGURE 39-27 Approach a helicopter on a grade only from the downhill side.

YOU are the Provider SUMMARY

1. What are the nine phases of an ambulance call?

The nine phases of an ambulance call are as follows: preparation for the call, dispatch, en route to the scene, arrival at the scene, transfer of the patient to the ambulance, en route to the receiving facility (transport), arrival at the receiving facility (delivery), en route to the station, and postrun. During the preparation phase, ensure that the ambulance and its contents are prepared and you are both mentally and physically prepared. During the dispatch phase, obtain important information regarding the medical or traumatic emergency. En route to the call, pay careful attention to the roadways and other potential hazards. After you arrive on scene, perform a scene size-up and take standard precautions. During the transfer phase, move your patient onto your stretcher and place the patient in the back of the ambulance. During the transport phase, transfer the patient to the appropriate facility as safely and comfortably as possible. During the delivery phase, turn over care of the patient to the ED staff. During the en route phase, depart from the facility and return to your assigned quarters, or remain available for another call. Finally, during the postrun phase, complete all documentation and clean and sanitize the ambulance.

2. Which of the nine phases of an ambulance call is the most important?

Each phase of an ambulance call is equally important and must be safely completed before you move on to the next phase. Failure to safely complete a phase will likely result in a negative outcome for the patient.

3. What are some potential distractions that may be found inside of the ambulance?

Some ambulances have MDTs and GPS that assist you in determining the location of the call. However, these devices, along with listening to the stereo,

talking on a mobile phone, and eating or drinking, create additional driving hazards. While the ambulance is in motion, focus on driving and anticipating roadway hazards while your partner operates the MDT, GPS, portable radios, or siren. Minimizing the potential distractions to the driver allows for a safer response and minimizes the potential for mishaps.

4. While en route, how should you prepare to assess and care for the patient?

Review dispatch information about the nature of the call and the location of the patient. Assign specific initial duties and scene management tasks to each team member, and decide what type of equipment to take initially. Depending on your operation procedures, you may also decide which stretcher to bring to the patient.

5. What equipment do you need to carry to the patient's side?

You will only need to carry your jump kit to the patient's side. The ambulance must be equipped with a portable, durable, and waterproof jump kit that you can carry to the patient. Think of the jump kit as the "5-minute kit," containing anything you might need in the first 5 minutes with the patient except for the semiautomated external defibrillator, possibly the oxygen cylinder, and the portable suctioning unit. The jump kit must be easy to open and secure.

6. What are some advantages of using an air ambulance?

Air ambulances have an advantage over ground transport in that they reduce transport time and may help the patient receive definitive treatment within the Golden Hour (sometimes called the Golden Period). The use of an air ambulance is warranted if the transport time to the hospital by ground ambulance is too long considering the patient's condition. Use

YOU are the Provider SUMMARY *continued*

of an air ambulance may be warranted if the patient has a spinal injury and the terrain over which the patient must be carried is very rough.

7. What are some disadvantages of using an air ambulance?

When deciding whether to request an air ambulance, you need to weigh several factors. First, consider the time needed to start the aircraft, load personnel and gear, travel to the scene, land the helicopter, and transfer the patient to the flight crew. Consider the weather; anything that interferes with visibility can make it too dangerous to fly. The terrain also may make it difficult to land the helicopter safely. Finally, consider whether a safe landing zone is available; uneven ground and loose objects may impact the ability of the aircraft to land safely.

8. What factors must you take into consideration when creating a landing zone?

Actions to take and considerations to include when selecting and establishing a landing zone include the following:

- Select a hard or grassy level surface that ideally measures 100 × 100 feet (30 × 30 m) and no less than 60 × 60 feet (18 × 18 m).
- Clear the area of any loose debris that could become airborne and strike the helicopter or the patient and flight crew.
- Survey the immediate area for any overhead hazards such as power lines or telephone cables, antennas, and tall or leaning trees.
- To mark the landing site, use weighted cones or position emergency vehicles at the corners of

the landing zone with headlights facing inward to form an X.

- Make sure that all nonessential people and vehicles are moved to a safe distance outside of the landing zone.
- If the wind is strong, then radio the direction of the wind to the flight crew.

9. What is the most important rule when working around helicopters on an emergency scene?

Keep a safe distance from the aircraft whenever it is on the ground and “hot,” which means when the tail rotor is spinning. Most of the time, the rotor blades will remain running because the flight crew does not generally expect to remain on the ground for a long time. Stay outside the landing zone perimeter unless directed by the pilot or a member of the flight crew to approach the aircraft. If you are asked to enter the landing zone, then stay away from the tail rotor; the tips of its blades move so rapidly that they are invisible. Never approach the helicopter from the rear, even if it is not running. If you must move from one side of the helicopter to another, then go around the front. Never duck under the body, the tail boom, or the rear section of the helicopter; the pilot cannot see you in these areas.

10. Who has ultimate control of the aircraft when on an emergency scene?

Regardless of the type of incident or the qualifications of the flight crew, the ultimate control of the aircraft rests solely on the pilot in command. The pilot in command makes the final decisions on all facets of aircraft operations.

Narrative

Dispatched to stand by at a structure fire. Fire department removed 50-year-old male from burning structure. Patient was unresponsive with partial-thickness (2nd-degree) burns to his face, chest, and arms. Patient presented with soot around his mouth and singed nasal hairs. Respirations were slow and shallow, and radial pulses were rapid and thready. Ventilations assisted with bag-mask device and 100% oxygen. Advised dispatch to call for air transport of patient. Landing zone established by law enforcement, and patient was transported to designated site by ambulance where emergency medical care was provided until the helicopter arrived. On arrival of flight crew, report given. Due to risk of airway compromise from inhalation injury, flight crew elected to manage airway with rapid sequence induction plus intubation prior to transport. Crew was assisted in loading patient into helicopter. Patient transported by flight crew to burn center.

End of report

Prep Kit

Ready for Review

- Modern ambulances are designed according to strict governmental regulations based on national standards.
- The six-pointed Star of Life emblem identifies vehicles as ambulances. It is often affixed to the sides, rear, and roof of the ambulance. Local or state regulatory authorities determine what emblems may be displayed on the side of an ambulance.
- An ambulance call has nine phases: preparation for the call, dispatch, en route to the scene, arrival at the scene, transfer of the patient to the ambulance, en route to the receiving facility (transport), arrival at the receiving facility (delivery), en route to the station, and postrun.
- Specific patient care supplies should be carried on the ambulance, including basic medical equipment, airway management equipment and ventilation devices, suctioning equipment, oxygen delivery equipment, CPR equipment, basic wound care supplies, splinting supplies, childbirth supplies, and appropriate medications. An AED, as permitted by medical control, should always be carried on the ambulance. A jump kit, patient transfer equipment, nonmedical supplies, and initial extrication and rescue equipment are also needed.
- Every ambulance must be staffed with at least one EMS provider in the patient compartment whenever a patient is being transported. However, two EMS providers are strongly recommended. Some services may operate with a civilian (non-EMS) driver and a single EMS provider in the patient compartment.
- Check all medical equipment and supplies at least daily, including all the oxygen supplies, the jump kit, splints, dressings and bandages, backboards and other immobilization equipment, and the emergency obstetric kit.
- During the postrun phase, complete and file any additional reports and inform dispatch of the status, location, and availability of the unit. Perform a routine inspection to ensure that the ambulance is ready to respond to the next call.
- Learning how to properly operate your vehicle is just as important as learning how to care for patients when you arrive on the scene.
 - The first rule of safe driving in an emergency vehicle is that speed does not save lives; good emergency medical care does.
 - The second rule is that the driver and all passengers must wear seat belts and shoulder restraints at all times.
- Drivers must be qualified to drive the ambulance, must be physically and emotionally fit, and must have the proper attitude. The driver must know and follow safe driving practices, including wearing a seat belt, using an appropriate speed, using the emergency warning lights and siren appropriately, and maintaining a cushion of safety.
- Air ambulances are used to evacuate medical and trauma patients.
- The two basic types of air medical units are fixed-wing aircraft (airplanes) and rotary-wing aircraft (helicopters).
 - Fixed-wing aircraft generally are used for interhospital patient transfers over distances greater than 100 to 150 miles (161 to 241 km).
 - Rotary-wing aircraft are more efficient for shorter distances.
- A medical evacuation is commonly known as a medevac and is generally performed exclusively by helicopters.
- You must follow certain safety rules when working around landing zones and helicopters. Familiarize yourself with these guidelines before working any call involving air transport.

Vital Vocabulary

acceleration The speeding up of an object.

air ambulances Fixed-wing aircraft (airplanes) and rotary-wing aircraft (helicopters) that have been modified for emergency medical care; used to evacuate and transport patients with life-threatening injuries to treatment facilities.

ambulance A specialized vehicle for treating and transporting sick and injured patients.

blind spots Areas of the road that are blocked from the driver's sight by their own vehicle or mirrors.

cleaning The process of removing dirt, dust, blood, or other visible contaminants from a surface.

chassis The structural framework of the ambulance.

chassis set The transfer of weight (center of mass) to different points on the chassis.

coefficient of friction A measure of the grip of the tires on the road.

CPR board A device that provides a firm surface under the patient's torso.

cushion of safety A defensive driving technique used to keep a safe distance between the ambulance and other vehicles on any side of the ambulance.

deceleration The slowing of an object.

decontaminated To have removed or neutralized radiation, chemical, or other hazardous

material from clothing, equipment, vehicles, and personnel.

disinfection The killing of pathogenic agents by direct application of chemicals.

first-responder vehicles Specialized vehicles used to transport emergency medical services equipment and personnel to the scenes of medical emergencies.

footprint The area of contact between the tire and the surface of the road.

friction The resistance to the motion of one body against another.

high-level disinfection The killing of pathogenic agents by using potent means of disinfection.

hydroplaning A condition in which the tires of a vehicle may be lifted off the road surface as water builds up under them, making the vehicle feel as though it is floating.

jump kit A portable kit containing items that are used in the initial care of the patient.

medevac Medical evacuation of a patient by helicopter.

spotter A person who assists a driver in backing up an ambulance to compensate for blind spots at the rear of the vehicle.

Star of Life The six-pointed star that identifies vehicles that meet federal specifications as licensed or certified ambulances.

sterilization A process, such as heating, that removes microbial contamination.

Chapter 40

Vehicle Extrication, Special Rescue, and Hazardous Materials

NATIONAL EMS EDUCATION STANDARD COMPETENCIES

EMS Operations

Knowledge of operational roles and responsibilities to ensure patient, public, and personnel safety.

Vehicle Extrication

- Safe vehicle extrication (pp 1927–1937)
- Use of simple hand tools (p 1934)

Hazardous Materials Awareness

- Risks and responsibilities of operating in a cold zone at a hazardous material or other special incident. (pp 1956–1958)

KNOWLEDGE OBJECTIVES

1. Explain the responsibilities of advanced emergency medical technicians (AEMTs) in patient rescue and extrication. (p 1926)
2. Compare the terms extrication and entrapment. (p 1927)
3. Discuss how to ensure safety at the scene of a rescue incident, including scene size-up and the selection of the proper personal protective equipment and additional necessary gear. (pp 1928–1929)
4. List the 10 phases of extrication and the role of AEMTs during each one. (pp 1927–1937)
5. Discuss the situational awareness factors AEMTs must use to ensure safety at the site of a vehicle extrication. (pp 1928–1929)
6. Name some vehicle safety system components that may be hazardous to both AEMTs and patients following a motor vehicle crash; include how AEMTs can mitigate these dangers. (pp 1930–1931)
7. Explain the different factors that must be considered before attempting to gain access to the patient during an incident that requires extrication. (pp 1933–1934)
8. Discuss patient care considerations related to assisting with rapid extrication, providing emergency care to a trapped patient, and removing and transferring a patient. (pp 1935–1937)
9. Contrast simple access and complex access in vehicle extrication. (p 1934)
10. Discuss situations that would require special technical rescue teams and the AEMTs role in these situations. (pp 1937–1938)
11. Describe tactical situations and the techniques used to stay safe at these incidents. (pp 1938–1940)

12. Describe some of the unique aspects of responding to a hazardous materials (hazmat) incident. (pp 1941–1942)
13. Know the entry-level training or experience requirements identified by the Hazardous Waste Operations and Emergency Response (HAZWOPER) regulation for AEMTs responding to a hazmat incident. (pp 1941–1942)
14. Describe the types of containers used to store hazardous materials. (pp 1944–1947)
15. Discuss the specific reference materials AEMTs can use to recognize a hazmat incident. (pp 1949–1954)
16. Explain the role of AEMTs during a hazmat incident before and after the hazmat team arrives and the precautions required to ensure the safety of civilians and responders. (pp 1954–1955)
17. Name the three control zones established at a hazmat incident, the characteristics of each zone, and the personnel who work within each one. (pp 1956–1958)
18. Describe the four levels of personal protective equipment required at a hazmat incident to protect responders from injury and contamination. (pp 1958–1959)
19. Explain patient care at a hazmat incident; include the special requirements that are necessary for those patients who require immediate treatment and transport prior to full decontamination. (pp 1959–1960)

SKILLS OBJECTIVES

1. Using an example, demonstrate how to correctly identify the US Department of Transportation's labels, placards, and markings used to designate hazardous materials. (pp 1947–1949)
2. Demonstrate the ability to use a variety of reference materials to identify a hazardous material. (pp 1949–1954)

Introduction

Rescue involves many different processes and environments, including vehicle, water, trench, tactical, and hazardous materials rescue. These kinds of rescues require training beyond the level of the advanced emergency medical technician (AEMT). For example, a motor vehicle crash (MVC) in which a fuel tank has ruptured creates a hazardous and potentially disastrous situation that requires the help of vehicle extrication and hazardous materials (hazmat) teams. Or, you may find yourself on the scene with a gunman who has begun to fire on people and is still at large. These incidents pose an increased risk to you and require the assistance of specialized teams.

There is always a chance that you may be the first emergency unit to arrive at the scene, and your initial actions may determine how efficiently the rescue is completed. This chapter begins with a brief discussion of safety at the scene of a rescue incident, followed by the basic concepts of patient rescue and extrication, and the hazards associated with responding to a hazmat incident.

Safety

You must always be prepared, mentally and physically, for any incident that requires rescue or **extrication** (the removal of a patient from

FIGURE 40-1 Proper protective equipment varies depending on the situation.

© Jones & Bartlett Learning. Courtesy of MIEMSS.

entrapment or from a dangerous situation or position). The most important part of your preparation is to think about your safety and the safety of your team. Safety begins with the proper mindset and the proper personal protective equipment (PPE; discussed later in this chapter).

The equipment that you use and the gear that you wear will depend on the situation you expect to encounter, as well as what you observe during your scene size-up (**FIGURE 40-1**). Such protective gear may include turnout gear, a helmet, hearing

protection, and a fire extinguisher. However, the importance of wearing blood- and fluid-impermeable gloves at all times during patient contact cannot be emphasized enough. If you are involved in an extrication, then wear a pair of leather gloves over your disposable gloves to protect yourself from injury when handling ropes, tools, broken glass, hot or cold objects, or sharp metal.

Fundamentals of Extrication

During all phases of rescue, your primary concern is safety, and your primary role is to provide emergency medical care and prevent further injury to the patient. You will provide care as extrication goes on around you unless this proves to be too dangerous for you or the patient. AEMTs may also be responsible for providing simple extrication when tools are not required. As discussed, extrication or disentanglement is the removal of a patient from entrapment or from a dangerous situation or position. **Entrapment** is a condition in which a person is caught within a closed area with no way out or has a limb or body part trapped. In the context of this chapter, in many cases, extrication refers to the removal of a patient from a wrecked vehicle. However, the same principles and concepts apply to other situations, such as removal of a patient from a collapsed building or from a trench.

There are 10 phases to the extrication process (**TABLE 40-1**). Many are similar to the phases of an ambulance call. Each phase is discussed, with emphasis on the phases in which you will participate. The phases of an ambulance call are outlined in Chapter 39, *Transport Operations*.

Preparation

Preparing for an incident requiring extrication involves preincident training with rescue personnel

TABLE 40-1 Ten Phases of Extrication

1. Preparation
2. En route to the scene
3. Arrival and scene size-up
4. Hazard control
5. Support operations
6. Gaining access
7. Emergency medical care
8. Removal of the patient
9. Transfer of the patient
10. Termination

Safety

During vehicle extrication, never position yourself between a patient and airbags! Even if the battery cables have been cut, there may still be enough of a charge left in the line to deploy an airbag, injuring you and the patient.

for the various types of rescue situations your team might face. Some are discussed later in this chapter. Just as you must check the equipment carried on the ambulance, rescue personnel must also routinely check the extrication tools and their response vehicle to ensure its proper operation. Such preparations reduce the possibility of equipment failure at an emergency scene.

YOU are the Provider

Part 1

Your ambulance is dispatched to an MVC on a rural road. On arrival, you are met by the incident commander (IC) who states his firefighters are attempting to gain access to the patient, who is trapped in the vehicle. As you approach the vehicle, you note that it is sitting on its roof, with massive damage to both sides of the vehicle, indicating it has rolled several times.

1. What are some hazards you may encounter with vehicle safety systems?
2. How should this vehicle be stabilized?

En Route to the Scene

The procedures and safety precautions similar to those discussed in the phases of an ambulance call are used when responding to a rescue call.

Arrival and Scene Size-up

Situational awareness allows you to recognize and understand potential threats and react proactively to avoid negative consequences (**FIGURE 40-2**). If you are the first to arrive on scene, then position the unit in a safe location that does not add a hazard to the scene and that also helps to protect the scene. If you are not the first to arrive, then choose a location that will allow safe access to the scene while leaving yourself a way out. Do not park in an area where you will be blocked in. If law enforcement or fire units have blocked the roadway, then position your unit so the back of the ambulance is pointing toward the scene to facilitate patient transport.

When you are on the scene of an MVC, use only essential warning lights. Too many lights can distract or confuse motorists. Many emergency responders have been injured on scenes when they were struck by passing vehicles. (Some local protocols require providers to reduce or turn off emergency lighting after the scene is secured; this may reduce the risk of a secondary crash.) If law enforcement is not on scene, then designate a traffic control person until law enforcement arrives. Before exiting your vehicle, check for any vehicles that might cause injury to you. Do not assume motorists will always heed the warning lights.

FIGURE 40-2 Assess the scene for any possible hazards and proactively manage them.

© Mike Legeros. Used with permission.

Safety

Wear a high-visibility reflective safety vest so you will be seen by fellow responders and motorists.

In the context of extrication, scene **size-up** is the ongoing process of information gathering and scene evaluation to determine appropriate strategies and tactics to manage an emergency, while paying attention to such hazards as downed power lines, leaking fluids, fire, and broken glass. One of the important responsibilities of scene size-up is to determine what, if any, additional resources you will need. These resources may include additional emergency medical services (EMS) units and personnel. If you are first on the scene, then you may need to initiate a rescue response or call for extrication equipment, fire service personnel and equipment, law enforcement, or specialized crews such as hazmat and utility departments.

A 360° walk around the scene will allow you to evaluate the hazards and consider potential injuries and determine the number of patients. If there is a large group of patients, then implement local mass-casualty incident protocols as necessary. During your walk, look for the following:

- Downed power lines
- Leaking fuel or other substances
- Smoke or fire
- Broken glass
- The mechanism of injury
- Trapped or ejected patients
- The number of patients and vehicles involved

This assessment can be performed in a matter of seconds, but is the most important step in protecting yourself and your crew.

On the scene of an MVC, it is important to note the physical damage to the structure of the vehicle or vehicles. For example, a bent steering wheel is a mechanism of injury for significant face and/or thoracic trauma. Imprints in the dashboard, which are usually the result of the knees striking it, indicate the potential for serious lower extremity injuries such as hip dislocations and fractures. Always lift up deployed airbags to see if there is deformity to the steering wheel or dashboard, which indicates the patient struck the structure after the airbag

deflated. Determine if the patient was restrained or not. An unrestrained patient may have contact injuries as well as secondary injuries. An unrestrained patient who is thrown forward may strike the windshield with the head, resulting in a spider web pattern of shattered glass and possible head, face, or neck injuries. Include any findings in your documentation and maintain a high index of suspicion, even if the patient does not present with significant obvious injuries.

Evaluate the need for additional resources, such as the following:

- Extrication equipment
- Fire suppression
- Law enforcement
- Hazmat units
- Utility companies
- Advanced life support unit or units
- Aeromedical transport

Look for leaked fuel and other flammable substances. Motor vehicles carry a variety of fuels and lubricants that pose a fire hazard. Some postcrash fires are started when sparks created during the crash ignite leaked fuel. A short in a vehicle's electrical system or a damaged battery may also cause a postcrash fire. These fires may trap the occupants of the vehicle and require fire suppression.

Environmental conditions can result in unique hazards at a crash scene. Crashes that occur in rain, sleet, or snow, for example, present an added hazard for rescue personnel and patients. Crashes that occur on hills are harder to handle than those that occur on level ground. Uneven terrain increases the potential for vehicles to roll over, requiring vehicles to be stabilized prior to gaining access.

Some crash scenes may present threats of violence. Intoxicated people or people who are upset with other motorists may pose a threat to you or to other people present at the scene. Be alert for weapons that civilians are carrying in vehicles.

Safety

The conditions responsible for an MVC may also cause other motorists to lose control of their vehicles and injure you. Maintain your situational awareness at all times.

Report to the IC (discussed later in the chapter) as soon as you arrive at a scene. Under the incident command system, the rescue operations are integrated as a separate group. You are a member of this group, and will provide care for the patient or patients when approved by the IC. You will coordinate your efforts with the rescue team and law enforcement and communicate with members of the rescue team throughout the extrication process. The incident command system is described in Chapter 41, *Incident Management*.

Stay focused. The rescue team is responsible for properly securing and stabilizing the scene or the vehicle, providing safe entrance and **access** to patients (the ability to reach the patient), extricating patients, ensuring patients are properly protected during extrication or other rescue activities, and providing adequate room so patients can be properly removed. You are responsible for assessing and providing immediate medical care, triaging patients, packaging the patient, providing additional assessment and care as needed once the patient has been removed, and providing transport to the emergency department (ED).

Safety

You may encounter "rolling" methamphetamine laboratories on roadways or in parking lots. Look for telltale signs such as large or older vehicles with paint peeling around the trunk area, accompanied by unusual odors. Use extreme caution when approaching these vehicles because there is the potential for an explosion and/or release of toxic gases.

Hazard Control

A variety of hazards may be present at a vehicle extrication scene. Law enforcement is responsible for traffic control and direction, maintaining order at the scene, investigating the crash or crime scene, and establishing and maintaining perimeters so that bystanders are kept at a safe distance and out of the way of rescuers. Firefighters are responsible for extinguishing any fire, preventing additional ignition, ensuring that the scene is safe, and managing any spilled fuel or other fluids.

Downed power lines are a common hazard at vehicle crash scenes. Never attempt to move

downed power lines. If power lines are touching or located in proximity to a vehicle involved in the crash, then instruct patients to remain in their vehicles until power is shut off by a utility company representative. If you are not the first at the scene, then there will be a protected area designated as the **safe zone**. Unless you are directed otherwise, you and the ambulance should remain in the safe zone, outside of the danger zone (**FIGURE 40-3**). A **danger zone** is an area where people can be exposed to hazards such as electric wires, sharp metal edges, broken glass, toxic substances, radiation, or ignition or explosion of hazardous materials.

Sometimes, an extrication scene is further complicated by the presence of **hazardous materials**. A hazardous material is any substance that is toxic, poisonous, radioactive, flammable, or explosive and can cause injury or death with exposure. In addition to posing a threat to you and others at the immediate scene, hazardous materials may pose a threat to a much larger area and population. Whenever there is a possibility that a hazardous material is involved, you must follow a number of additional special procedures. These procedures are discussed later in this chapter.

Bystanders and family members can also create hazards. If they are allowed to get too close, they are at risk of injury and may also interfere with the overall management of the incident. For these reasons, the danger zone is off-limits to bystanders. Help to set up and enforce this zone. If you arrive before the rescue team, then coordinate crowd control with law enforcement officials.

On the scene of an MVC, the actual vehicle can be a hazard. An unstable vehicle on its side or roof can be a danger to you. Rescue personnel can

Words of Wisdom

Managing a difficult bystander may prove especially challenging when the person claims to have medical credentials. If a physician attempts to intervene, inform medical control immediately. Communication between medical control and the physician may reduce the risk of confrontation.

stabilize the vehicle with a variety of jacks or cribbing (wooden blocks). Prior to attempting to gain access to a vehicle involved in a crash, ensure the vehicle is in “park” with the parking brake set and the ignition turned off. Both battery cables should be disconnected, negative side first, to minimize the possibility of sparks or fire. Other hazards include vehicles with headrests that deploy in the event of a crash and vehicles that are already on fire or are leaking fuel. Do not approach a vehicle that is on fire or leaking fuel without proper turnout gear, and never use flares around these vehicles.

Words of Wisdom

When possible, collect all electronic keys and move them away from the vehicle to prevent accidental ignition if the starter button is accidentally depressed.

Vehicle Safety Systems

A variety of safety systems are included in modern vehicles. Although many of these devices are useful when the vehicle is in motion, they can become hazards after the vehicle has been involved in a crash.

FIGURE 40-3 Unless you are directed otherwise, remain outside the danger zone.

© Jones & Bartlett Learning.

Words of Wisdom

A vehicle crash scene can present many hazards to EMS providers and patients, including fuel spills that pose fire and explosion risks, downed power lines that pose electrical hazards, broken glass and torn metal, and exposure to potentially infectious body fluids. Your safety at every type of emergency scene begins with, and depends on, your scene size-up. What you see at the scene helps you determine which PPE to use and whether to call for additional or specialized assistance.

Shock-absorbing bumpers provide vehicle protection from low-speed impact. Following a front- or rear-end crash, the shock absorbers within these bumpers may be compressed or “loaded.” Avoid standing directly in front of such bumpers, and always approach vehicles from the side, because the shock absorbers can release and injure your knees and legs.

Manufacturers are mandated to incorporate supplemental restraint systems such as airbags and seat belt pretensioners into their vehicles. Airbags fill with a nonharmful gas on impact and quickly deflate after the crash. Airbag components and harnesses are labeled with yellow tags or warning labels. Airbags are located in the steering wheel and the dashboard in front of the passenger, and they deploy when the vehicle is struck from the front or rear. Additional airbags may be present to protect the driver and passengers from side impacts. These airbags may be located in the doors, interior roof-lines, roof pillars, or seatbacks. Airbags will normally deploy and deflate before you arrive on the scene. However, airbags have inflated and caused injury while EMS providers were providing patient care. Airbags may deploy on impact with hot gas from a pyrotechnic charge or a high-pressure inert gas from a charged cylinder that may be remote. Use caution when working in damaged vehicles in which airbags have not inflated. Maintain at least a 5-inch (13-cm) clearance around side-impact airbags that have not deployed, a 10-inch (25-cm) clearance around driver-side airbags that have not deployed, and 20-inch (50-cm) clearance around passenger-side airbags that have not deployed.

Some airbag manufacturers use powder-like lubricants such as cornstarch or talcum powder to

Safety

Before beginning any extrication operations, airbags must be disabled. This may be specific to the vehicle, as described in the *Emergency Response Guide*. If providers cut or disconnect the 12-volt power supply, they must wait for residual voltage to dissipate, which can generally take 30 seconds.

Never cut until you verify that there are no airbags or cylinders located in a cut zone.

aid in deployment and lubricate the fabric of the airbag.¹ You may notice a haze similar to smoke inside vehicles in which these airbags have deployed. Although nontoxic, the appropriate protective gear, including eye protection, will reduce the potential for irritation from these substances.

Seat belt pretensioners tighten the seat belt when sensors are triggered. They are chambers of combustible gas with explosive igniter material that force the piston in the chamber to be driven upward at a high speed. Damage to this chamber can result in injury to the patient or rescuers.

Alternative Fuel Vehicles

With advances in automotive technology, EMS responders should keep in mind that some vehicles on the road are powered by an alternative fuel. An **alternative fuel vehicle** is a vehicle that uses anything other than a petroleum-based motor fuel (gasoline or diesel fuel) to propel a motorized vehicle.² These vehicles may be powered by alternative fuels such as propane, natural gas, methanol, or hydrogen. Other alternative fuel vehicles may be powered by electricity (battery electric vehicles) or a combination of electricity and fuel (hybrid electric vehicles).

Alternative fuel vehicles are usually identified by markings on the vehicle. You should not approach these vehicles without proper PPE. Toxic fumes and vapors from battery electric or hybrid electric vehicle batteries can be carried in smoke or steam. Do not approach the vehicle if you detect an unusual odor, and retreat if you experience burning in your eyes or throat, until the scene is safe. If they have not been notified previously, call dispatch to request additional assistance from the fire department and/or hazmat team. An electric or hybrid

FIGURE 40-4 The battery pack installed in a Toyota Prius.

© Jones & Bartlett Learning.

vehicle may still move without making any sound. The first action is making sure the vehicle is in park and wheels are chocked to prevent any unintended movement while trying to access the patient.

Although each type of electric drive vehicle (hybrid/electric vehicle or pure battery electric vehicle) has its own unique features, one feature is common throughout—the need for properly trained responders to disable the high-voltage battery pack by removing the 12-volt source to prevent electrical shock or further fire or explosion (**FIGURE 40-4**).

The batteries may not be located in the engine compartment, but in other areas, such as the trunk or under the seats. Furthermore, there also may be more than one battery present. You must remain vigilant and be aware of their inherent dangers. Electric drive vehicle batteries have a higher voltage than traditional automotive batteries, and it may take up to 10 minutes for a high-voltage system to de-energize after the main battery is turned off. Avoid contact with high-voltage wires (typically orange) and components throughout the rescue (**FIGURE 40-5**).³ Do not cut or disconnect any orange connectors or cables.

Safety

A fire fueled by ethanol or methanol burns bright blue and can be very difficult to see on a clear day. Methanol burns without smoke, and therefore may seem to burn with an invisible flame in bright light.

FIGURE 40-5 High-voltage wiring.

Words of Wisdom

Tips for Managing Alternative Fuel Vehicle Hazards

- Look for markings specific to alternative fuel vehicles, and call early for assistance.
- Ensure that the ignition is off and key fobs are at least 30 feet (9 m) away from the vehicle on smart key and push-button ignition systems.
- Do not use flares to mark off the incident scene; use nonsparking markers such as cones.
- Determine if the vehicle is stable and ensure all hazards are identified and controlled or eliminated.
- Be aware of the potential for toxic vapors, gases, or fumes even if no fire is present. Also remember that during daylight hours it may be very difficult to see flames from a fire fueled by methanol or ethanol.
- Avoid contact with any fluids leaking from the vehicle.
- Determine if the high-voltage battery pack has been disabled and the 12-volt source removed on electric drive vehicles.
- Call for hazmat teams as soon as possible, and set up a safety zone around the perimeter to keep bystanders and responders safe.

Support Operations

Support operations include lighting the scene, establishing tool and equipment staging areas, and marking helicopter landing zones. Fire and rescue personnel will work together on these functions.

Gaining Access

A crucial phase of extrication is gaining access to the patient. Never attempt to gain access to the patient or enter the vehicle until you are sure any hazards have been identified and properly controlled or eliminated. When there is an IC present, you will be authorized to enter only when these considerations have been met.

The exact way to gain access depends on many factors, including the terrain and the weather. It is up to you to identify the safest, most efficient way to gain access (**FIGURE 40-6**). Darkness, uneven terrain, tall grass, shrubbery, or wreckage may make patients hard to find. Multiple vehicles with multiple patients may be involved. If this is the case, then you should locate and rapidly triage each patient to determine who needs urgent care. This step is important before you proceed with any treatment and patient packaging. Take these factors into account during your scene size-up. Remember, scene size-up is a continuing process, because the situation often changes. As a result, you may need to change your plans for gaining access and providing treatment.

To determine the exact location and position of the patient, you and your team should consider the following questions:

- Is the patient in a vehicle or in some other structure?
- Is the vehicle or structure severely damaged?

FIGURE 40-6 Identify the safest, most efficient way to gain access.

© Brian Logan Photography/Shutterstock.

- What hazards exist that pose a risk to the patient and responders?
- In what position is the vehicle? On what type of surface? Is the vehicle stable or is it likely to roll over?

Also consider the patient's injuries and their severity. You may have to change your course of action as you learn more about the patient's condition. For example, do not try to access the patient until you are sure the vehicle is stable and hazards have been identified and deemed safe. Hazards might include electrical or gas lines. Decide if you will need additional resources such as extrication equipment or a hazmat team, fire department, law enforcement, utility company, or air transport. Notify the dispatcher.

What should you do if you have to remove a patient quickly because the environment is threatening or you need to perform cardiopulmonary resuscitation (CPR)? CPR is not effective when the patient is in a sitting position or lying on the soft seat of a vehicle. In these instances, you and your team may have to use the rapid extrication technique to move a patient from a sitting position inside a vehicle to a supine position on a long backboard. A team of responders who are experienced in using this technique should be able to perform rapid extrication in 1 minute or less. Use the rapid extrication technique only as a last resort. Emergency moves, such as the rapid extrication technique, are discussed in Chapter 6, *Lifting and Moving Patients*.

While you are gaining access to the patient and during extrication, make sure the patient remains safe. Always talk to the patient and describe what you are going to do before you do it and as you are doing it, even if you think the patient is unresponsive (**FIGURE 40-7**). In many instances, you or your partner may be providing cervical spine immobilization or other care during extrication. EMS personnel should wear proper protective gear while in the working area. During vehicle extrication, both you and the patient should be covered by a thick, fire-resistant canvas or blanket for protection from broken glass, flying particles, tools, or other hazards during any cutting or forceful extrication maneuvers. A backboard may also be used as a protective shield. Keep heat, noise, and force to a minimum. Use only what is necessary to extricate the patient safely.

FIGURE 40-7 Always explain to the patient why you are there and what you are doing.

© Keith D. Cullom.

Removing a patient from the vehicle can be an intensive process for the rescue team, requiring much time and equipment. It is generally a multi-step process that requires stabilizing the vehicle, gaining access to the patient to initiate care, and then disentangling the patient from the wreckage. It is a coordinated effort between the caregivers and those performing the extrication. Constant communication is a must.

Simple Access

Your first step is **simple access**—accessing the patient as quickly and simply as possible without using any tools or force. Although motor vehicles are built for easy entry and exit, it may be necessary to use tools or other forcible entry methods during vehicle extrication.

Words of Wisdom

Remember: Try before you pry!

Although the rescue team is responsible for providing the entrance you need to gain access to the patient, there will be some situations when the rescue team has not yet arrived and delayed access to the patient could be life threatening. During a vehicle extrication, simple hand tools, such as hammers, center punches (to break side or rear windows), pry bars, come-alongs, and hacksaws,

FIGURE 40-8 Try to open every door to gain access before you use forced entry.

© TFoxFoto/Shutterstock.

are usually stored on the ambulance for you to use. Whenever possible, you should first try to unlock the doors or open the windows (or ask the patient to perform these actions). Try to open every door to gain access before you break any windows or use other methods of forced entry (**FIGURE 40-8**). Enter through the doors when there is no danger to the patient.

When accessing the patient, look for potential hazards such as undeployed airbags and seat belt pretensioners.

Complex Access

Complex access requires special training and the use of special tools and equipment during vehicle extrication, such as pneumatic and/or hydraulic devices, to break windows or perform other forcible means of entry. The advanced extrication skills typically performed by a rescue team rather than EMS providers include the following:

- Brake and gas pedal displacement
- Dashboard roll-up
- Door removal
- Roof opening and removal
- Seat displacement
- Steering column displacement
- Steering wheel cutting

Emergency Care

Providing medical care to a patient who is trapped in a vehicle is principally the same as providing care to any other patient. Unless there is an immediate

threat of fire, explosion, or other danger, once you gain entrance and access to the patient and ensure scene safety, perform a primary assessment and perform any critical interventions before further extrication begins, as follows:

1. Provide manual stabilization to protect the cervical spine, as needed.
2. Open the airway.
3. Provide high-flow oxygen as needed.
4. Assist or provide for adequate ventilation.
5. Control any significant external bleeding.
6. Treat all critical injuries.

If the patient has obvious, life-threatening external hemorrhage, then address it first (even before airway and breathing) and control it quickly.

Safety

Place a rigid backboard between the windshield and the patient during vehicle extrication to help protect the patient and you while glass is broken and metal is cut.

Good communication among team members and clear leadership are essential to ensure safe, efficient provision of proper emergency care. Although your input at the scene is important, one member of your team must be clearly in charge. The team leader's assessment of the patient and the situation will determine the way in which medical care, packaging, and transport will proceed. Customarily, the senior medical person is responsible for this role. If no IC is present, then follow local guidelines. (Crew resource management is discussed in detail in Chapter 15, *BLS Resuscitation*. Chapter 41, *Incident Management*, discusses team leaders and their roles within the incident command system.)

A lack of identifiable leadership at the scene hinders the rescue effort and patient care. Leaders should be identified as part of a larger incident command system. They should be medically trained and qualified to judge the priorities of patient care, and they must also be experienced in extrication.

Removal of the Patient

In the case of a vehicle extrication, work with rescue personnel to coordinate the best route for removal.

Street Smarts

Bystanders may use the cameras on their phones to record the extrication and removal of the patient. Be respectful of your patient's privacy as you transfer the person from the entrapment into the back of the ambulance.

Whereas one accident may require removal of the patient through the driver's door, a similar crash may require complete removal of the vehicle's roof. Removing a patient from a motor vehicle is an intensive, multistep process in terms of the number of rescuers involved, the equipment used, and the effort required to prevent further injury or harm.

As a part of your assessment, participate in the preparation for patient removal. Determine how urgently the patient must be extricated; where you should be positioned to best protect the patient during extrication; and, once the patient has been freed, how you will best move the patient from the patient's current location onto the backboard and onto the stretcher. Carefully examine exposed areas of the patient's body to determine the extent of injury and whether there is a possibility of internal bleeding. If possible, evaluate sensation in trapped areas to determine whether increased pain indicates that an object is pressing on or impaled in the patient during extrication.

During this time, the rescue team is assessing exactly how the patient is trapped and determining the safest, easiest way to extricate the person. Your input is essential so the patient's injuries are considered as the rescue team plans a move that protects the patient from further harm. Reevaluate whether the patient needs to be immediately removed by using manual stabilization and the rapid extrication technique, or whether the patient's condition and the scene allow for immobilization using an extrication vest or short backboard before the patient is moved further. If one of these devices is used, then remember to *always move the patient and not the device*. In most cases, it is impractical and difficult to properly apply extremity splints while inside a vehicle. Extremity injuries can generally be rapidly supported and immobilized while the patient is being removed by securing an injured arm to the body and, if a leg is injured, securing one leg to the other. This will be adequate management

until the patient is secured to the backboard or time allows for a more detailed assessment and splinting of each injury.

Once the extrication plan has been devised and everyone understands what will be done, you should determine how best to protect the patient. For example, often you or your partner will be placed in a vehicle to monitor the patient's condition and well-being as the vehicle is being forcibly cut, bent, or disassembled. Wear proper protective clothing, and protect the patient from harm.

Naturally, your safety and that of the patient are paramount during this process. Extrication is often extremely noisy, and appropriate hearing protection should be worn by you and the patient. Make sure you communicate effectively with the patient and with the rescue team so you can let the rescue team know immediately if it is necessary for them to stop.

Transfer of the Patient

Once the patient has been freed, rapidly assess any other patients who were previously inaccessible, and perform a complete primary assessment. Ensure the spine is manually stabilized, and apply

Street Smarts

The team leader must determine the appropriate method for extricating or removing a patient from entrapment. Team members should listen to determine their individual roles; offer closed-loop communication, acknowledging they understand their roles; and bring to the team leader's attention any circumstance that could injure the team or further injure the patient.

a cervical collar if this was not previously done (**FIGURE 40-9**).

Move the patient in a series of smooth, slow, controlled steps, with designated stops to allow for repositioning and adjustments. Ensure there are sufficient personnel to perform the move without causing further injury to the patient. One person should be in charge of the move and plan and verbalize the exact steps and pathway that you will follow in moving the patient from sitting in the vehicle to lying supine on the backboard or stretcher.

YOU are the Provider

Part 2

The firefighter in charge of extrication informs you that this is a hybrid electric vehicle, and all batteries have been disconnected. He also states the patient is currently pinned by his legs in the overturned vehicle, and that it will take approximately 15 to 20 minutes to remove the patient. You ask if it is possible to get into the rear seat of the vehicle in an attempt to maintain spinal precautions; however, the firefighter tells you that one of his men is already in the rear of the vehicle immobilizing the patient's cervical spine. Because most of the extrication efforts are taking place on the driver's side, you proceed to the passenger side to attempt to speak with the patient. The patient is alert and oriented. He reports he is unable to feel his legs. He pleads with you to get him out. You note the patient is still wearing his seat belt and that the driver's side airbag has deployed.

Recording Time: 1 Minute

Appearance	Fair
Level of consciousness	Alert and oriented
Airway	Patent
Breathing	Clear and equal, 20 breaths/min
Circulation	Warm and dry

- What are the hazards that may present with hybrid electric vehicles?
- What are the differences between simple access and complex access?

FIGURE 40-9 Once the patient has been accessed, rapidly assess the patient and ensure the spine is manually stabilized. Apply a cervical collar if this was not previously done.

© Keith D. Gullom.

Choose a path that requires the least manipulation of the patient or equipment. Once you are sure that everyone understands the steps and is ready, you can move the patient safely. Move only on the team leader's command and move the patient as a unit. While moving the patient, continue to protect the person from any hazards.

Once the patient has been placed on the stretcher, continue with any additional assessment and treatment that was deferred. If it is extremely cold or hot, raining, or snowing, then load the stretcher and patient into the climate-controlled ambulance before continuing assessment and treatment. If the patient's condition requires you to initiate transport without further delay, then provide only the additional medical care that is essential or necessary to package the patient. Perform the remaining steps while you are en route to the hospital.

Termination

Termination involves returning the emergency units to service. For rescue units, this may be a time-consuming process. All equipment used on the scene, including hydraulic, electric, and hand tools, must be checked before the vehicle is reloaded. Whereas some tools require only generalized cleaning, others may need refueling and checking of the various fluid levels.

You are required to check the ambulance thoroughly, replacing used supplies and decontaminating the unit as required by bloodborne pathogen standards.

Finally, rescue units and medical units are required to complete all necessary reports.

Specialized Rescue Situations

On most calls, you can drive the ambulance to or within a short distance of the patient's location and, with simple or complex access, you can reach and treat the patient. However, in some situations, the patient can be reached only by teams that are trained in making special technical rescues. Specialized skills of these teams include the following:

- Special weapons and tactics (SWAT)
- Missing person search and rescue
- Technical rope rescue (low- and high-angle rescue)
- Mountain-, rock-, and ice-climbing rescue
- Cross-field and trail rescue (park rangers)
- Water and small craft rescue
- White water rescue
- Dive rescue
- Cave rescue
- Confined space rescue
- Ski slope and cross-country or trail snow rescue (ski patrol)
- Lost person search and rescue
- Structural collapse rescue
- Trench rescue
- Mine rescue

A **technical rescue situation** may contain hidden dangers, and special technical skills and equipment are needed for personnel to safely enter and move around. It is not safe to include any personnel who do not have the necessary special training and experience in such a rescue. A **technical rescue group** is made up of people from one or more departments in a region who are trained and on call for certain types of technical rescues. Many members of a technical rescue group are also trained as emergency medical responders (EMRs), emergency medical technicians (EMTs), AEMTs, or paramedics so they can provide the necessary immediate care when they can safely reach the patient.

If a technical rescue group is necessary but is not present when you arrive, then immediately

Words of Wisdom

Even when the technical rescue group includes a paramedic or physician, generally only essential, simple care is provided until the group members can bring the patient to the nearest safe and stable setting, known as the staging area.

check with the **incident commander (IC)** to make sure the group has been summoned and is en route to your location. The IC is the individual who has overall command of the incident in the field (**FIGURE 40-10**). If no IC is present, then follow local guidelines. (Chapter 41, *Incident Management*, discusses this in more detail.)

When you arrive at a scene where a technical rescue is already in progress, you will usually be met by a member of the technical rescue group and directed or led to the staging area. If the staging area is some distance from the road, then you may need to leave the ambulance on the road. If it is impractical to use a stretcher, then bring a backboard and/or basket stretcher or similar rescue stretcher to carry the patient back to the waiting ambulance. Take all of the jump kits and other equipment you may need to treat and immobilize the patient at the staging area.

As soon as the technical rescue group brings the patient to the staging area, perform a primary assessment and, after providing the treatment indicated, package the patient without delay. Although

FIGURE 40-10 The incident commander is the person who has overall command of the scene.

© Glen E. Ellman.

you are responsible for the patient's care, it usually requires a cooperative effort by the technical rescue group and EMS personnel to carry the patient to the waiting ambulance. Consider using air medical transport if the patient will need to be carried or transported a great distance.

Tactical Emergency Medical Support

A steady increase in violence throughout the country has resulted in AEMTs taking precautions to ensure personal safety. A **tactical situation** is a hostage, robbery, or other situation in which armed conflict occurs. An **active shooter** is a gunman who has begun to fire on people and is still at large. These scenes are especially tense because someone who appears to be a released hostage could, in fact, be the perpetrator or an accomplice. These incidents pose an increased risk to you and require the use of specialized law enforcement tactical units, or the **special weapons and tactics (SWAT) team**.

Words of Wisdom

During a mass shooting or active shooter situation, law enforcement is the lead agency. You must follow their instructions at all times for the safety of you, your partner, and the public.

EMS providers who respond to a tactical situation must prepare, plan, and train for these complex, difficult, violent incidents and need to know how to stay safe. Turn off lights and siren when you are nearing the scene, and do not use outside radio speakers. Know the difference between cover and concealment, and the difference between objects that provide cover and those that provide concealment. **Cover** refers to a barrier that protects against gunfire. Whether a barrier qualifies as cover depends on the caliber of the firearm and the distance between the shooter and the barrier. For example, a mailbox may provide cover from a small-caliber firearm such as a .22-caliber rifle, but not from a .308-caliber rifle. When using a vehicle as cover, placing the engine block or the wheels and axles between oneself and the shooter provides better

cover than the doors. Tall grass, shrubbery, and dark shadows that limit your visibility to someone are considered areas of **concealment**. When cover is not readily available, use concealment to provide protection. Remember, people are going to need your help; do not do anything that could get you or your partner injured.

As an AEMT, you must take direction from law enforcement personnel on the scene and you may even be instructed as to *whom* to treat and *when* a patient can be treated. This is not your normal triage situation because law enforcement has absolute control of the scene, and they may dictate that you initiate or withhold treatment not based on medical necessity, but rather on public safety. Carefully document any requests or demands you receive that deviate from your local protocols.

Words of Wisdom

Consider having a training session with your local police department on how to assess a police officer who has been shot. Specifically, address how to remove full-body armor and the officer's duty belt. The protocol for who removes the officer's weapons, and how, should be established before an incident occurs.

Determine the location of the command post, where command, coordination, control, and communication are centralized, and report to the IC for instructions. The command post is usually located in an area that cannot be seen by the suspect and is out of range of possible gunfire. Remain in this area and do not roam around. Nearby areas may be visible to the suspect, and you could be injured. The IC will need to identify the specific location of the incident and determine a safe location (staging area) where you can meet SWAT team members or tactical EMS providers, who will bring the patient to you for treatment and transport to a medical facility. The IC should also determine a safe route to this meeting point.

To save valuable time in critical situations, designate primary and secondary helicopter landing zones if your region uses aeromedical evacuation. The closest hospital, burn center, and trauma center should be identified. The route of travel to these facilities should also be noted. Many of these

measures are incorporated into the operational plan used by tactical EMS providers. If tactical EMS providers are used in your jurisdiction, then coordinate with them on your arrival at the command post.

Words of Wisdom

Tips for Responding to a Tactical Situation

- Turn off lights and siren as you approach the scene.
- Do not turn on the vehicle's outside speakers. Turn down the volume of any radios that you are carrying.
- Do not look around the sides or over the top of any building or structure that may be serving to provide cover.
- When exiting the ambulance, stay low, and remain near the side of the vehicle unless you are directed to another place of safety. Utilize cover or concealment techniques as necessary.
- Request direction from the IC.
- Stand by at the staging area to treat and package injured patients after the SWAT team, tactical EMS providers, or law enforcement officers have evacuated them.
- Leave only after the IC has verified that it is safe for the ambulance to move.
- Follow the specific route indicated by the IC or law enforcement officer when you are exiting the scene. Proceed slowly for a good distance from the incident perimeter before turning on your emergency lights and siren.

Tactical Medicine

Owing to the high potential for injuries during tactical situations, many communities have incorporated tactical medicine into their SWAT teams.

Tactical medicine is emergency medical care provided by specially trained EMTs, AEMTs, paramedics, nurses, and even physicians during a tactical situation. In most jurisdictions, tactical EMS providers care for law enforcement teams making tactical entry into violent situations; however, these specially trained responders can also provide care for barricaded patients, patients being held hostage, and other special operations in which a provider without special training might not be able to work. Tactical medicine is a crucial link in providing medical care in hostile situations.

Training in this evolving EMS subspecialty is widely available from reputable training centers. The training goes well beyond the practices seen in standard emergency medical care. Thus, the techniques used may not seem appropriate or adequate. For example, spinal motion restriction is not used within an unsecured area where gunfire is a risk because the time and manpower necessary to completely secure a patient to a backboard may expose responders and the patient to injury or death from gunfire (**FIGURE 40-11**). Such altered standards of care are similar to those used by military EMS providers on the battlefield and are not used in “standard” situations encountered by AEMTs.

Search and Rescue

When someone is lost in the outdoors and a search effort is initiated, an ambulance is usually summoned to the incident command post (location of the IC) or the staging area. Each search team is organized to include a member who is trained at the EMR, EMT, or AEMT level, carrying the essential equipment to provide essential, immediate care. Your role, and that of the other AEMTs who arrived with the ambulance, is to stand by at the command post or staging area until the missing person or people have been found.

As soon as you arrive at the scene and have been briefed on the situation, you should isolate and prepare the equipment you will need to carry to the patient’s location; this will save time once the patient has been found or if a member of the search team is

FIGURE 40-11 Tactical EMS providers move a downed officer; only the most basic medical care is provided in an unsecured area.

© Jones & Bartlett Learning.

injured. Leave the prepared carry-in equipment, including a backboard and other equipment you will need to immobilize the patient, in the back of the ambulance until the patient has been found. If the ambulance needs to be relocated, then the equipment will not need to be reloaded and will not be left behind. You will usually be given a portable radio that is tuned to the search frequency so you can monitor the progress of the search and communicate with and be contacted by those in charge of the search operation.

Sometimes, you may be asked to stay with relatives of the missing person who are at the scene. Find out from relatives whether the missing person has any medical history that may need to be addressed, and pass this information on to those who are in charge of the search. Unless you have been instructed otherwise, only the IC should communicate any news or progress of the search to the family. For this reason, ensure your radio is set at a discreet volume.

Words of Wisdom

Never leave your ambulance to assist in the search for a missing person. Once found, the person will be brought to you (or you will be brought to the individual) for care. Leaving your post may lead to a delay in care for the individual.

Once the missing person has been found, you will be guided by search personnel to that location or a prearranged intersecting point where the patient will be carried, which allows you to begin treatment more quickly. Ensure the carry-in equipment is evenly distributed among personnel and that the pace is such that all can easily stay together. Also, consider relocating the ambulance or, if available, driving a four-wheel drive, all-terrain vehicle or snowmobile to decrease the time and effort needed to reach and carry out the patient. As with other technical rescues, although EMS will assume the responsibility for patient care once they are at the patient’s side, a cooperative effort between the EMS and search teams is necessary to safely carry the patient to the staging area and waiting ambulance.

Trench Rescue

Trench rescue refers to rescue for incidents involving cave-ins and collapses. Owing to the physical

forces involved, many of these incidents have poor outcomes. Trench collapses usually involve large areas of falling dirt that weigh approximately 100 pounds per cubic foot (1,600 kg per cubic meter). Patients with thousands of pounds of dirt resting on their chests cannot fully expand their lungs and may become hypoxic.

The risk of a secondary collapse during the rescue operation is of concern to rescue personnel and to the AEMTs. Safety measures can reduce the potential for injury from this and other hazards. When arriving at the scene of a cave-in or trench collapse, response vehicles should be parked at least 500 feet (152 m) from the scene. Because vibration is a primary cause of secondary collapse, turn off all vehicles, including on-scene construction equipment. In addition, divert all road traffic from the 500-foot safety area. Other hazards include exposed or downed electric wires and broken gas or water lines. In addition, construction equipment at the collapse site may be unstable and could fall into the cave-in or trench site.

Any witnesses to the incident should be identified. They may be valuable in providing information on the number of patients and their location within the collapsed area. Anyone who is not trapped should be assisted from the area. At no time should medical or rescue personnel enter a trench deeper than 4 feet (1 m) without proper shoring (temporary supports to prevent collapse) in place.

During the extrication of any survivors from a cave-in or trench collapse site, trained medical personnel will provide most medical care. Be prepared to receive patients once they have been extricated from the site.

Structure Fires

In most areas, an ambulance is dispatched with the fire department apparatus to any structure fire, whether or not any injuries are reported. A fire in a house, apartment building, office, school, plant, warehouse, or other building is considered a structure fire. When responding to a major fire scene, you should determine whether, because of the fire, any special route will be necessary. Once you arrive at the scene, you should ask the IC where the ambulance should be parked. It is essential that the ambulance be parked far enough away from the fire to be safe from the flames or a collapsing building.

Ensure the ambulance does not block or hinder other arriving equipment or become blocked in by other equipment or hose lines. However, the ambulance should be close enough to be visible and easily accessible for patients. The fire officer who is the IC will determine this location.

Safety

Hazards such as fire, infectious disease, and electricity are not the only risks to your safety during an emergency response. Some calls will involve violence against rescuers. This may be a formal tactical situation or a "simple" call involving assault, possible alcohol or drug abuse, and/or a domestic dispute. Your training, your attitude when responding to calls, and your daily EMS procedures should take these risks into account.

Your next step is to determine whether there are any injured patients at the scene or whether you have been called to stand by. A number of ambulances may be dispatched to a major fire to ensure one or more units will always remain immediately available at the scene if others leave to transport the injured.

As with other technical rescue situations, search and rescue in a burning building requires special training and equipment. Search and rescue is performed by teams of firefighters wearing full turnout gear and a **self-contained breathing apparatus (SCBA)** and carrying tools and fully charged hose lines. These teams will bring patients out of the burning building to the area where the ambulance is staged. Therefore, unless you are instructed otherwise, always stay with the ambulance. Do not leave even after the fire is extinguished, in case a firefighter becomes injured during salvage and overhaul. The ambulance should leave the scene only if transporting a patient or if the IC has released it.

Introduction to Hazardous Materials

A hazardous material is any material that poses an unreasonable risk of damage or injury to people, property, or the environment if it is not properly controlled during handling, storage, manufacture, processing, packaging, use and disposal, and

transportation. Your training has taught you that rapid response to the scene of a crash can save lives. However, when you arrive at the scene of a possible hazmat incident, you must first step back and assess the situation. This can be very stressful for you, particularly if you can see a patient. However, rushing into an unsafe scene can have catastrophic results. If you are overcome by a hazardous substance, not only will patients suffer because you will be unable to assist them, but you will also place a strain on the system because you will require emergency care.

Because of the unique aspects of responding to and working at a **hazardous materials (hazmat) incident**, the Occupational Safety and Health Administration (OSHA) has published a set of guidelines known as Hazardous Waste Operations and Emergency Response (HAZWOPER). All providers, including AEMTs, must meet specific additional training requirements before becoming involved in hazmat incidents. These training requirements are published in 1910.120(q)(6)(i): First Responder Awareness Level. This text does not include the skills and information necessary to meet those requirements. You need to check with your agency for information about specific awareness-level training.

On the basis of the HAZWOPER regulation, first responders at the awareness level should have sufficient training or experience to objectively demonstrate competency in the following areas:

- An understanding of what hazardous substances are and the associated risks
- An understanding of the potential outcomes of an incident
- The ability to recognize the presence of hazardous substances
- The ability to identify the hazardous substances, if possible
- An understanding of the role of the first responder awareness individual in the emergency response plan
- The ability to determine the need for additional resources and to notify the communication center

Recognizing a Hazardous Material

Recognizing a hazmat incident, determining the identity of the material or materials, and understanding the hazards involved often require some

Safety

Methamphetamine is a stimulant and an illegal recreational drug, commonly referred to as meth. This drug has gained popularity due to its increased accessibility and relatively low cost. Meth is manufactured in illegal labs with highly volatile chemicals in a process known as cooking. The toxic fumes from meth labs not only create respiratory hazards, but may also ignite, causing fires or explosions. Exposure to the toxic fumes may cause irritation to the nose and throat, headaches, confusion, altered mental status, dizziness, nausea and/or vomiting, and respiratory problems. People who cook meth are often exposed to the toxins or have burn injuries because the risk of explosion is high.

You may find meth labs anywhere in the country and in virtually any setting, including homes, garages, abandoned trailers, or the trunk of a vehicle. Therefore, your potential for contact with a meth lab is high.

When responding to a general medical call, you may not realize that you are responding to a hazardous area. A house with all of the windows covered; glass cookware with a powdery residue; or a strong smell of an unusual odor like ammonia, cat urine, or nail polish remover is a sign of a potential meth lab. If you have any suspicions that you may be in the presence of a meth lab, leave the area immediately and notify law enforcement to secure the scene and arrange for decontamination and cleanup.

detective work. Train yourself to take the time to look at the whole scene so you can identify the crucial visual indicators and consider this information with what is known about the problem.

Hazardous materials may be involved in any of the following situations (**FIGURE 40-12**):

- A truck or train crash in which a substance is leaking from a tank truck or railroad tank car
- A leak, fire, or other emergency at an industrial plant, refinery, or other complex where chemicals or explosives are produced, used, or stored
- A leak or rupture of an underground natural gas pipe
- Deterioration of underground fuel tanks and/or seepage of oil or gasoline into the environment
- Buildup of methane or other by-products of waste decomposition in sewers or sewage-processing plants
- An MVC in which a gas tank has ruptured

A

B

FIGURE 40-12 Two examples of hazardous materials incidents.

A: Courtesy of Rob L. Jackson/US Marines; **B:** Courtesy of George Roarty/Virginia Department of Emergency Management.

Initially, it is important to approach the scene from a safe location and direction. Start with the traditional rules of staying uphill and upwind. It may also be wise to use binoculars and view the scene from a safe distance. Be sure to question anyone involved in the incident—a wealth of information may be available to you if you ask the right person. Take enough time to assess the scene and interpret other clues such as discolored pavement, dead grass or animals, visible vapors or puddles, or

labels that may help identify the presence of a hazardous material. Once you have a basic idea of what happened or determine that danger may be present, you can begin to formulate a plan for addressing the incident.

Safety

When responding to a potential hazmat incident, use the rule of thumb method of response until the scene can be deemed safe. Hold your arm straight in front of you with your fist closed and your thumb up. Close one eye. Your thumb should completely block your view of the scene. If you can see any portion of the scene around your thumb, then you are too close!

Occupancy and Location

A wide variety of chemicals are stored in warehouses, hospitals, laboratories, industrial complexes, residential garages, bowling alleys, home improvement centers, garden supply stores, restaurants, and scores of other facilities or businesses in your response area. So many different chemicals exist in so many different locations that you could encounter almost anything during any type of emergency situation. The location and type of building are two good indicators of the possible presence of a hazardous material. For example, a warehouse is more likely than a school to have materials that could be hazardous.

Senses

Another way to detect the presence of hazardous materials is to use your senses, although this technique must be used carefully to avoid exposure. The senses that can be safely used are those of sight and sound. Initially, the farther you are from the incident, the safer you will be. Using any of your senses that bring you in proximity to the chemical should be done with caution or avoided. When it comes to hazmat incidents, “leading with your nose” is not a good tactic, but using binoculars from a distance is.

Clues that are seen or heard may provide warning information from a distance, enabling you to take precautionary steps. The presence of vapor clouds or hazmat placards or labels at the scene, for example, is a signal to yourself and others to move

to a place of safety; the sound of an alarm from a toxic gas sensor in a chemical storage room or laboratory may also serve as a warning to retreat. Some highly vaporous and odorous chemicals (chlorine and ammonia, for example) may be detected by smell a long way from the actual point of release.

Containers

In basic terms, a **container** is any vessel or receptacle that holds a material. Often the container type, size, and material of construction provide important clues about the nature of the substance inside. Nevertheless, do not rely solely on the type of container when making a determination about hazardous materials.

Red phosphorus from a drug laboratory, for example, might be found in an unmarked plastic container. In this case, there may not be legitimate markings to alert you to the possible contents. Gasoline or waste solvents may be stored in 55-gallon (208-L) steel drums. Sulfuric acid, at 97% concentration, could be found in a polyethylene drum that might be colored black, red, white, or blue. In most cases, there is no correlation between the color of the drum and the possible contents. The same sulfuric

acid might also be found in a 1-gallon (3.8-L) amber glass container. Steel or polyethylene drums, bags, high-pressure gas cylinders, railroad tank cars, plastic buckets, aboveground and underground storage tanks, cargo tanks, and pipelines are all representative examples of how hazardous materials are packaged, stored, and shipped (**FIGURE 40-13**).

FIGURE 40-13 Drums may be constructed of many different types of materials, including cardboard, polyethylene, and stainless steel. The drum shown here is made of polyethylene.

YOU are the Provider

Part 3

Knowing that extrication is going to be prolonged and that the patient is in a critical situation, you discuss the possibility of a helicopter request with the IC. He agrees with your request; you proceed to contact dispatch to request that a helicopter be sent to the scene. Once dispatch has informed you the helicopter is en route with an approximately 10-minute ETA, you inform the IC of the need to establish a safe landing zone. He advises you that he will have his firefighters establish a landing zone that measures 100 × 100 feet (30 × 30 m), approximately 200 yards (183 m) from the vehicle. You proceed back to the patient's side and begin a limited assessment. He states he does not believe that he experienced a loss of consciousness and that he has no pain, only a lack of feeling in his legs, which are trapped by the steering column. You are able to slide in through the broken passenger window and place the patient on oxygen at 15 L/min via a nonrebreathing mask. You obtain the following vital signs:

Recording Time: 5 Minutes

Respirations	20 breaths/min, irregular
Pulse	105 beats/min, regular
Skin	Warm and dry
Blood pressure	110/76 mm Hg
Oxygen saturation (SpO₂)	99% on 15 L/min
Pupils	Pupils Equal, Round, and Reactive to Light and Accommodation (PERRLA)

- What should you do as the patient is being extricated from the vehicle?
- How does rapid extrication differ from other methods of patient removal?

FIGURE 40-14 A series of chemical storage containers.

© Ulrich Mueller/Shutterstock.

Some very recognizable chemical containers, such as 55-gallon (208-L) drums and compressed gas cylinders, can be found in almost every type of manufacturing facility. Materials stored in a cardboard drum are usually in solid form. Stainless steel containers hold particularly dangerous chemicals, and cold liquids are kept in containers designed to maintain the appropriate temperature (**FIGURE 40-14**).

One way to distinguish containers is to divide them into two categories based on their capacity: bulk and nonbulk storage containers.

Safety

When you consider locations for possible hazmat incidents, do not limit your thinking. You may be surprised at how many different kinds of containers you may find in your area.

Container Volume

Bulk storage containers include fixed tanks, highway cargo tanks, rail tank cars, totes, and intermodal tanks. In general, bulk storage containers are found in buildings that rely on and need to store large quantities of a particular chemical. Most manufacturing facilities have at least one type of bulk storage container. Often these bulk storage containers are surrounded by a supplementary

FIGURE 40-15 A tote is a commonly encountered bulk storage vessel.

Courtesy of Tank Service, Inc.

containment system to help control an accidental release. **Secondary containment** is an engineered method to control spilled or released product if the main containment vessel fails. A 5,000-gallon (18,927-L) vertical storage tank, for example, may be surrounded by a series of short walls that form a catch basin around the tank.

Large-volume horizontal tanks are also common. When stored above ground, these tanks are referred to as aboveground storage tanks; if they are placed underground, they are known as underground storage tanks. These tanks can hold a few hundred gallons to several million gallons of product and are usually made of aluminum, steel, or plastic.

Another commonly encountered bulk storage vessel is the tote, also referred to as an intermediate bulk container. Totes have capacities ranging from 119 gallons to 703 gallons (450 to 2,661 L); the most common sizes are 350 and 550 gallons (1,325 and 2,082 L). These portable plastic tanks are surrounded by a stainless steel web that adds both structural stability and protection to the container. They can contain any type of chemical, including flammable liquids, corrosives, food-grade liquids, or oxidizers (**FIGURE 40-15**).

Shipping and storing totes can be hazardous. These containers are often stacked atop one another and moved with a forklift, and a mishap with the loading or moving process can compromise the tote. Because totes have no secondary containment system, any leak has the potential to create a large puddle. In addition, the steel webbing around the tote makes it difficult to access and patch leaks.

FIGURE 40-16 An intermodal tank.

Courtesy of UBH International Ltd.

Intermodal tanks are both shipping and storage vessels. They hold between 5,000 and 6,000 gallons (18,927 and 22,712 L) of product and can be pressurized or nonpressurized. Intermodal tanks can also be used to ship and store gaseous substances that have been chilled until they liquefy, such as liquid nitrogen. In most cases, an intermodal tank is shipped to a facility where it is stored and used and then returned to the shipper for refilling. Intermodal tanks can be shipped by all methods of transportation: air, sea, and land (**FIGURE 40-16**).

Nonbulk Storage Vessels

Essentially, **nonbulk storage vessels** are all types of containers other than bulk containers. Nonbulk storage vessels can hold from a few ounces to 119 gallons (450 L) of product and include vessels such as drums, bags, compressed-gas cylinders, cryogenic containers, and more. Nonbulk storage vessels hold commonly used commercial and industrial chemicals such as solvents, industrial cleaners, and compounds. This section describes the most common types of nonbulk storage vessels.

Drums

Drums are easily recognizable, barrel-like containers (**FIGURE 40-17**). They are used to store a wide variety of substances, including food-grade materials, corrosives, flammable liquids, and grease. Drums may be constructed of low-carbon steel, polyethylene, cardboard, stainless steel, nickel, or other materials. Generally, the nature of the chemical dictates the construction of the storage drum. Steel

FIGURE 40-17 An open-head drum has a lid that is fastened with a ring that is tightened with a clasp or a nut-and-bolt assembly.

Courtesy of Globalindustrial.com.

utility drums, for example, hold flammable liquids, cleaning fluids, oil, and other noncorrosive chemicals. Polyethylene drums are used for corrosives such as acids, bases, oxidizers, and other materials that cannot be stored in steel containers. Cardboard drums hold solid materials such as soap flakes, sodium hydroxide pellets, and food-grade materials. Stainless steel or other heavy-duty drums generally hold materials too aggressive (ie, too reactive) for either plain steel or polyethylene.

Bags

Bags are commonly used to store solids and powders such as cement powder, sand, pesticides, soda ash, and slaked lime. Storage bags may be constructed of plastic, paper, or plastic-lined paper. Bags come in different sizes and weights, depending on their contents.

Pesticide bags must be labeled with specific information. You can learn a great deal from the label, including the following details:

- Name of the product
- Active ingredients
- Hazard statement
- The total amount of product in the container
- The manufacturer's name and address

- The Environmental Protection Agency (EPA) registration number, which provides proof that the product was registered with the EPA
- The EPA establishment number, which shows where the product was manufactured
- Signal words to indicate the relative toxicity of the material:
 - Danger—Poison: Highly toxic by all routes of entry
 - Danger: Severe eye damage or skin irritation
 - Warning: Moderately toxic
 - Caution: Minor toxicity and minor eye damage or skin irritation
- Practical first aid treatment description
- Directions for use
- Agricultural use requirements
- Precautionary statements such as mixing directions or potential environmental hazards
- Storage and disposal information
- Classification statement on who may use the product

In addition, every pesticide label must carry the statement, “Keep out of reach of children.”

Carboys

Some corrosives and other types of chemicals are transported and stored in vessels called **carboys** (FIGURE 40-18). A carboy is a glass, plastic, or steel container that holds 5 to 15 gallons (19 to 57 L) of product. Glass carboys are often placed in a

FIGURE 40-18 A carboy is used to transport and store corrosive chemicals.

Courtesy of EMD Chemicals, Inc.

protective wood, foam, fiberglass, or steel box to help prevent breakage. For example, nitric acid, sulfuric acid, and other strong acids are often transported and stored in thick glass carboys protected by a wooden or polystyrene (Styrofoam) crate to shield the glass container from damage during normal shipping.

Cylinders

Several types of **cylinders** are used to hold liquids and gases. Uninsulated compressed gas cylinders are used to store substances such as nitrogen, argon, helium, and oxygen. They come in a range of sizes. As an AEMT, you are very familiar with the shape of a cylinder: it holds the oxygen for your patients.

Transportation and Facility Markings

The Department of Transportation Marking System

The presence of labels, placards, and other markings on packages, boxes, and containers can often enable you to identify a released chemical. When used correctly, marking systems indicate the presence of a hazardous material from a safe distance and provide clues about the substance.

The US Department of Transportation (DOT) marking system is an identification system characterized by labels, placards, and markings (FIGURE 40-19).

This marking system is used when materials are being transported from one location to another in the United States. The same marking system is also used in Canada and Mexico.

Placards are diamond-shaped indicators (10.75 inches [27 cm] per side) that are placed on all four sides of highway transport vehicles, railroad tank cars, and other forms of transportation carrying hazardous materials (FIGURE 40-20). Labels are smaller versions (4 inches [10 cm] per side) of placards; they are placed on the four sides of individual boxes and smaller packages being transported.

Placards, labels, and markings are intended to give a general idea of the hazard inside a particular container or cargo tank. A placard identifies the broad hazard class (flammable, poison,

© Mark Winfrey/Shutterstock.

corrosive) to which the material inside belongs. A label on a box inside a delivery truck, for example, relates only to the potential hazard inside that particular package.

Other Considerations

In most cases, the package or cargo tank must contain a certain amount of hazardous material before a placard is required. For example, the “1,000-pound rule” applies to blasting agents, flammable and nonflammable gases, flammable/combustible liquids, flammable solids, air-reactive solids, oxidizers and organic peroxides, poison solids, corrosives, and miscellaneous (class 9) materials. Placards are required for these materials only when the shipment weighs more than 1,000 pounds (454 kg).⁴ Commercial package delivery services often carry small amounts of hazardous materials that fall below that weight limit. The vehicle exterior will not display placards to warn you of the danger.

Conversely, some chemicals are so hazardous that shipping any amount of them requires the use of labels or placards. These materials include

explosives, poison gases, water-reactive solids, and high-level radioactive substances. A four-digit United Nations number may be required on some placards. This number identifies the specific material being shipped; a list of United Nations numbers is included in the *Emergency Response Guidebook*.⁵

The National Fire Protection Association 704 Marking System

The National Fire Protection Association (NFPA) 704 standard, *Standard System for the Identification of the Hazards of Materials for Emergency Response*, classifies hazardous materials for fixed facilities that store hazardous materials.⁶ The standard uses a diamond-shaped symbol that is broken into four smaller diamonds, and each division is color-coded to represent a particular property or characteristic of a substance or a group of substances (**FIGURE 40-21**). The three basic principles of the symbol are designated as they relate to hazards: health (blue), flammability (red), and instability/reactivity (yellow). The degree of severity or hazard for each principle is indicated using a numerical rating of 0 (no hazard) to 4 (severe risk) (**TABLE 40-2**). For your safety, know the type and degree of health, fire, and reactive hazard protection you need to operate safely near these substances before you enter the scene.

Words of Wisdom

To accurately compare and contrast the DOT marking system and NFPA 704 system, remember this important difference:

- The DOT hazardous materials marking system is used when materials are being transported from one location to another.
- The NFPA 704 hazard identification system is designed for fixed-facility use.

Note that all health hazard levels, with the exception of 0, require respiratory and chemical protective gear that is not standard on most ambulances and specialized training. **TABLE 40-3** further describes the PPE required for each hazard class.

Reference Materials

Numerous reference materials are available to the responder. The following sections describe some of these resources. Other references include

The Emergency Response Guidebook

The DOT's *Emergency Response Guidebook (ERG)* offers a certain amount of guidance for responders operating at a hazmat incident (**FIGURE 40-22**). This guide is updated every 3 to 4 years and provides information on approximately 4,000 chemicals. The

TABLE 40-2 Hazard Levels in the NFPA Hazard Identification System**Flammability Hazards (Red Diamond) ♦**

- 4
Materials that will rapidly or completely vaporize at atmospheric pressure and normal ambient temperature, or that are readily dispersed in air and that will burn readily
- 3
Liquids and solids that can be ignited under almost all ambient temperature conditions
- 2
Materials that must be moderately heated or exposed to relatively high ambient temperatures before ignition can occur
- 1
Materials that must be preheated before ignition can occur
- 0
Materials that will not burn under typical fire conditions

Health Hazards (Blue Diamond) ♦

- 4
Materials that, under emergency conditions, can be lethal
- 3
Materials that, under emergency conditions, can cause serious or permanent injury
- 2
Materials that, under emergency conditions, can cause temporary incapacitation or residual injury
- 1
Materials that, under emergency conditions, can cause significant irritation
- 0
Materials that, under emergency conditions, would offer no hazard beyond that of ordinary combustible material

Instability Hazards (Yellow Diamond) ♦

- 4
Materials that in themselves are readily capable of detonation or of explosive decomposition or reaction at normal temperatures and pressures
- 3
Materials that in themselves are capable of detonation or explosive decomposition or explosive reaction but require a strong initiating source or that must be heated under confinement before initiation
- 2
Materials that readily undergo violent chemical change at elevated temperatures and pressures
- 1
Materials that will not burn. Materials that are normally stable, but can become unstable at elevated temperatures and pressures
- 0
Materials that in themselves are normally stable, even under fire exposure conditions, and are not reactive with water

Special Hazards (White Diamond) ♦

- ACID Acid
- ALK Alkali
- COR Corrosive
- OX Oxidizer
- W Reacts with water

TABLE 40-3 PPE Required for Each Hazard Level

Level	Health Hazard	Protection Needed
0	Little or no hazard	None
1	Slightly hazardous	SCBA (Level C suit) only
2	Slightly hazardous	SCBA (Level C suit) only
3	Extremely hazardous	Full protection, with no exposed skin (Level A or B suit)
4	Minimal exposure causes death	Special hazmat gear (Level A suit)

Abbreviations: PPE, personal protective equipment; SCBA, self-contained breathing apparatus

US DOT and the Secretariat of Communications and Transportation of Mexico, along with Transport Canada, jointly developed the *ERG*. You can download a free copy of the *ERG* via the Pipeline and Hazardous Materials Safety Administration website. A mobile app is also available.

Safety Data Sheets

A common source of information about a particular chemical is the **safety data sheet (SDS)** specific to that substance (**FIGURE 40-23**).⁷ Safety data sheets (SDSs) were called material safety data sheets (MSDSs) before OSHA implemented the United Nation's Globally Harmonized System of Classification and Labeling of Chemicals (GHS) in 2012. According to the DOT, the GHS system is an international guideline that aims to harmonize the classification and labeling systems for all sectors involved in the life cycle of a chemical. This includes production, storage, transport, workplace use, consumer use, and presence in the environment. The terms SDS and MSDS are used interchangeably; however, SDSs have a structured format and require information that MSDSs were not required to have. SDSs also include the use of nine recently introduced GHS symbols (to see the symbols, refer to the latest version of the *ERG*). Essentially, SDSs are designed to provide basic information about the chemical makeup of a substance, the potential hazards it presents, appropriate first aid in the event of an exposure, and other pertinent data for safe handling of the material for both workers and emergency personnel. SDSs have a 16-part format and may include the following details:⁸

1. Identification
2. Hazard(s) identification
3. Composition/information on ingredients
4. First aid measures
5. Firefighting measures
6. Accidental release measures
7. Handling and storage

Nitrogen, refrigerated liquid

Safety Data Sheet P-4630

This SDS conforms to U.S. Code of Federal Regulations 29 CFR 1910.1200, Hazard Communication.

15. Regulatory information
16. Other information

All facilities that use or store chemicals are required by law to have an SDS on file for each chemical used or stored in the facility. Many sites, but especially those that stock many different chemicals, may keep this information archived on a computer database. Although SDSs are not a definitive response tool, they are a key piece of the puzzle and the key to preventing exposures and accidents. SDSs can also be obtained from the transporting vehicle.

Shipping Papers

Shipping papers are required whenever materials are transported from one place to another. They

include the names and addresses of the shipper and the receiver, identify the material being shipped, and specify the quantity and weight of each part of the shipment. Shipping papers for road and highway transportation are called **bills of lading** or **freight bills** and are located in the cab of the vehicle (**FIGURE 40-24**). Drivers transporting chemicals are required by law to have a set of shipping papers on their person or within easy reach inside the cab at all times.

CHEMTREC

Located in Falls Church, VA, the **Chemical Transportation Emergency Center (CHEMTREC)**, now operated by the American Chemistry Council, is a clearinghouse of technical chemical information. Since 1971, this public service hotline has served as an invaluable information resource for first responders of all disciplines to help mitigate incidents involving hazardous materials. The emergency response number for CHEMTREC is available through the CHEMTREC website

YOU are the Provider

Part 4

After approximately 10 minutes, the fire department has removed the driver's side door and freed the patient's legs from under the steering column, allowing you unrestricted access to the patient. You move to the driver's side and quickly apply a cervical collar on the patient, while instructing the firefighter in the backseat to maintain manual stabilization. You slide a long backboard under the patient's head and explain to the patient, as well as the firefighters, that you are going to remove the seat belt, gently slide the patient onto the backboard, and secure him. Once everyone in attendance has agreed with your method for extrication, you quickly remove the seat belt and lower the patient onto the waiting backboard where he is properly secured. You perform another rapid scan and find no visible trauma; however, the patient remains without motor or sensation to his lower extremities. With the assistance of the firefighters, you quickly carry the patient to the stretcher and place him in the back of the ambulance, awaiting the flight crew. Once inside the back of the ambulance, you establish intravenous (IV) access and infuse fluids at a to-keep-open (TKO) rate. Once the helicopter has arrived at the scene, you provide a report to the flight paramedic and assist in loading the patient into the helicopter. After the helicopter has departed the scene, you go back to the overturned vehicle and look for any equipment that you may have left behind.

(www.chemtrec.com). CHEMTREC can provide technical chemical information via telephone, fax, or other electronic media. It also offers a phone conferencing service to connect you with thousands of shippers, subject matter experts, and chemical manufacturers.

When you call CHEMTREC, have the following basic information ready:

- The name of the material or materials involved in the incident (if known)
- Name of the caller and callback telephone number
- Description of incident and actions taken
- Shipper or manufacturer of the chemical or chemicals (if known)
- Container type and number of containers
- Railcar or vehicle markings or numbers
- The shipping carrier's name
- Recipient of material
- Location, time, weather at the scene

When you are speaking with CHEMTREC personnel, spell out all chemical names; if using a third party, such as a dispatcher, it is vital that you confirm all spellings to avoid misunderstandings. One number or letter out of place could throw off all subsequent research. When in doubt, be sure to obtain clarification.

Identification of Hazardous Materials

Unfortunately, even with all of these resources, identifying materials can still be difficult. Little consistency is used on labels and placards, and sometimes dishonest transporters will not label containers or vessels appropriately. The laws and regulations that cover labeling of packages and transport vehicles can also be misleading. As discussed previously, in most cases, the package or tank must contain a certain amount of a hazardous material before a placard is required. For example, because of the small

quantities of hazardous materials that are involved, a truck carrying 99 pounds (45 kg) of hazmat No. 1 and 99 pounds (45 kg) of both hazmat No. 2 and hazmat No. 3 may not be required by law to display any labels or placards. The truck may show only a “Please drive carefully” placard, implying that it carries no hazardous materials. Therefore, a crash involving this truck is a serious situation, but you would not necessarily know this if you relied on labels and placards. Always maintain a high index of suspicion when approaching the scene of a truck or train tanker incident.

Some substances are not hazardous on their own; however, when mixed with another substance, they may become highly toxic. There may not be regulations against carrying such substances together on one truck or railroad car (or adjacent tank cars). The driver of a commercial truck and the conductor of a train, however, must carry shipping papers that identify what is being transported in their care. These shipping papers may be your first clue that there is a possible hazmat incident; however, depending on the nature of the incident, the papers may not be available to you.

In the event of a leak or spill, a hazmat incident is often indicated by the presence of the following:

- A visible cloud or strange-looking smoke resulting from the escaping substance
- A leak or spill from a tank, container, truck, or railroad car with or without hazmat placards or labels
- An unusual, strong, noxious (harmful), harsh odor in the area

To indicate the presence of normally odorless toxic gases or fluids during a leak or spill, manufacturers may add a substance that produces a strong noxious odor. However, a large number of hazardous gases and fluids are essentially odorless (or do not have a distinctive unpleasant smell) even when a substantial leak or spill has occurred. In some incidents, a large number of people are exposed and may be injured or killed before the presence of a hazmat incident is identified. If you approach a scene where more than one person has collapsed or is unresponsive or in respiratory distress, then assume there has been a hazmat leak or spill and that it is unsafe to enter the area.

It is important for you to understand the potential danger of hazardous materials and know how to

operate safely at a hazmat incident. If you do not follow the proper safety measures, then you and many others could end up needlessly injured or dead. Your safety and that of your team, the other responders, and the public must be your most important concern.

There will be times when the ambulance is the first to arrive at the scene. If, as you approach the scene, you see any signs that suggest a hazmat incident has occurred, then stop at a safe distance and park upwind or uphill from the incident. After rapidly sizing up the scene, call for a hazmat team. If you do not recognize the danger until you are too close, then leave the area immediately. Once you have reached a safe place, rapidly assess the situation and provide as much information as possible when calling for the hazmat team, including your specific location, the size and shape of the containers of the hazardous material, and what you have observed and have been told has occurred. Do not reenter the scene, and do not leave the area until you have been cleared by the hazmat team, or you may contribute to the situation by spreading hazardous materials. Finally, do not allow civilians to enter the scene, if possible. No one should enter the area without the proper protective equipment, respiratory protection, or training.

Above all, avoid all contact with the material!

Hazmat Scene Operations

Once you have recognized the incident as one involving hazardous materials and have called for the hazmat team, focus your efforts on activities that will ensure the safety and survival of the greatest number of people. Use the ambulance's public address system to alert people who are near the scene and direct them to move to a location where they

Safety

Safety considerations at hazmat scenes differ considerably from those involved in emergency response in general. A hazmat scene requires you to have an even higher degree of alertness than usual to avoid entering a dangerous environment and to help others avoid it. There is also a need to prevent the spread of contamination to yourself and your ambulance. Understanding these two concepts is a good start toward safe operations in the presence of hazardous materials.

will be sufficiently far from danger. With the aid of others on your team, set up a perimeter to stop traffic and people from entering the area.

Establishing Control Zones

Managing a hazmat incident by setting control zones and limiting access to the incident site helps reduce the number of civilians and responders who may be exposed to the released substance. **Control zones** are established at a hazmat incident based on the chemical and physical properties of the released material, the environmental factors at the time of the release, and the general layout of the scene. Of course, isolating a city block in the busy downtown area of a large city presents far different challenges than isolating the area around a rolled-over cargo tank on an interstate highway. Each situation is different, requiring flexibility and thoughtfulness. Securing access to the incident helps ensure no one accidentally enters a contaminated area.

If the incident takes place inside a structure, then the best place to control access is at the normal points of ingress and egress (entry and exit)—doors. Once the doors are secured so that no unauthorized personnel can enter, appropriately trained emergency response crews can begin to isolate other areas as appropriate.

The same concept applies to outdoor incidents. The goal is to secure logical access points around the hazard. Begin by controlling intersections, on and off ramps, service roads, and other access routes to the scene. Police officers should assist by diverting traffic at a safe distance outside the hazard area. They should block off streets, close intersections, and redirect traffic as needed.

During a long-term incident, highway department or public works department employees may be called on to set up traffic barriers. Whatever methods or devices are used to restrict access, they should not limit or prevent a rapid withdrawal of responders from the area.

It is not uncommon to set large control zones at the onset of an incident, only to discover that the zones may have been established too liberally. At the same time, control zones should not be defined too narrowly (**FIGURE 40-25**). As the IC gets more information about the specifics of the chemical or material involved, the control zones may be expanded or reduced. Ideally, the control zones will

FIGURE 40-25 Control zones spread outward from the center of a hazardous materials incident.

© Jones & Bartlett Learning.

be established in the right place, geographically, the first time. Wind shifts are a common reason why control zones are modified during the incident. If there is a prevailing wind pattern in your area, then factor that information into your decision-making process when it comes to control zones.

Typically, control zones at hazmat incidents are labeled as *hot*, *warm*, or *cold*. You may also discover that other terms are used, such as *exclusionary zone* (hot zone), *contamination reduction zone* (warm zone), and *outer perimeter* (cold zone). In any case, make sure you understand the terminology used in your jurisdiction. Be prepared to discover that different jurisdictions may use terminology and setup procedures unlike the ones used in your agency. As long as you understand the concepts behind the actions and remember that safety is the main focus, the act of setting up and naming zones can remain flexible.

The **hot zone** is the area immediately surrounding the release, which is also the most contaminated area. Its boundaries should be set large enough that adverse effects from the released substance will not affect people outside of the hot zone. An incident involving a gaseous substance or a vapor, for example, may require a larger hot zone than one involving a solid or nonvolatile liquid leak. In some cases, atmospheric monitoring, plume modeling, or reference sources such as the *ERG* may prove useful in helping to establish the parameters of a hot zone. Specially trained responders, in accordance with their level of training, should be tasked with using these tools. Keep in mind that the physical characteristics of the released substance will significantly affect the size and layout of the hot zone. In addition, all specially trained responders entering the hot zone should avoid contact with the product

to the greatest extent possible—an important goal that should be clearly understood by those entering the hot zone. Adhering to this policy makes the job of decontamination easier and reduces the risk of cross-contamination.

Personnel accountability is important, so access into the hot zone must be limited to only the people necessary to control the incident. All personnel and equipment must be decontaminated when they leave the hot zone. This practice ensures that contamination is not inadvertently spread to “clean” areas of the scene.

The **warm zone** is where personnel and equipment transition into and out of the hot zone. It contains control points for access to the hot zone as well as the decontamination area. Only the minimum number of personnel and the equipment necessary to perform decontamination or support those operating in the hot zone should be permitted in the warm zone.

A patient's skin and clothing may contain hazardous material, so the **decontamination area** is set up in the warm zone. The decontamination area is the designated area where contaminants are removed before an individual can go to another area. **Decontamination** is the process of removing or neutralizing and properly disposing of hazardous materials from equipment, patients, and rescue personnel. The decontamination area must include special containers for contaminated clothing and special bags to isolate each patient's personal effects safely until they can be decontaminated (**FIGURE 40-26**). The area will also contain a number of special facilities to thoroughly wash and rinse patients and backboards. The water that is used must be captured and delivered into special sealable containers.

Anyone who leaves the hot zone must pass through the decontamination area. Firefighters' and hazmat team members' outer protective gear is rinsed and washed in the decontamination area before it is removed (**FIGURE 40-27**). To prevent needless

FIGURE 40-26 Patients should be decontaminated before they are taken to treatment areas.

Safety

As an AEMT, your job is to report to a designated area outside of the hot and warm zones and provide triage, treatment, transport, or rehabilitation when hazmat team members bring patients to you.

contact and transmission of splash or residues, different personnel are used in the decontamination and treatment areas. Do not move into the decontamination area unless you are properly trained and equipped. Wait for the patients to be brought to you.

Beyond the warm zone is the **cold zone**. The cold zone is a safe area where personnel do not

Safety

All levels of protection require you to wear gloves. Two pairs of rubber gloves are needed for protection in case one pair must be removed because of heavy contamination.

need to wear any special protective clothing for safe operation. Personnel staging; the command post; EMS providers; and the area for medical monitoring, support, and/or treatment after decontamination are all located in the cold zone.

Personal Protective Equipment Level

Personal protective equipment (PPE) levels indicate the amount and type of protective gear needed to prevent injury from a particular substance. Chemical protective clothing is rated for its effectiveness in several different ways. The EPA defines levels of protection using an alphabetic system (**FIGURE 40-28**).⁹

Level A protection requires a fully encapsulated, chemical-resistant garment that completely envelops the wearer and the respiratory apparatus, gloves, boots, and communications equipment.

Use Level A protection when the hazardous material identified requires the highest level of skin, respiratory, and eye protection.

Level B protection requires chemical-resistant clothing, boots, gloves, and SCBA. The kind of gloves and boots worn depends on the chemical identified. Use this type of PPE when the type and atmospheric concentration of the hazardous material identified require a high level of respiratory protection but less skin protection is needed. The defining piece of equipment with Level B protection is an SCBA or some other type of supplied-air respirator (a respirator that obtains its air through a hose from a remote source such as a compressor or storage cylinder).

Level C protection requires standard work clothing plus chemical-protective clothing and gloves. Use respiratory protection that filters all inhaled outside air. Level C protection is appropriate when the type of airborne substance is known, its concentration is measured, the criteria for using air-purifying respirators are met, and skin and eye exposure is unlikely.

Level D protection is the lowest level of protection. This level of protection typically requires coveralls, work shoes, hard hat, gloves, and standard work clothing such as an AEMT uniform. Use only when the atmosphere contains no known hazard and when work functions preclude splashes, immersion,

A

B

C

D

FIGURE 40-28 Four levels of protection. **A.** Level A protection. **B.** Level B protection. **C.** Level C protection. **D.** Level D protection.

or the potential for unexpected inhalation or contact with hazardous levels of chemicals. Use Level D protection only for nuisance contamination (such as dust); it should not be worn on any site where respiratory or skin hazards are known to exist.

Caring for Patients at a Hazmat Incident

Generally, hazmat team members who are trained in prehospital emergency care will initiate emergency medical care for patients who have been exposed to a hazardous material. However, because of the dangers, time constraints, and bulky protective gear that team members wear, it is practical only to provide the simplest assessment and essential care in the hazard zone and the decontamination area. In addition, to avoid entrapment and spread of contaminants, no bandages or splints are applied—except pressure dressings or tourniquets that are needed to control bleeding—until the “clean” (decontaminated) patient has been moved to the treatment area. Therefore, when you are providing care in the treatment area, assess and treat the patient in the same way as you would a patient who has not been previously assessed or treated.

Your care of patients at a hazmat incident must address the following:

- Any trauma that has resulted from other related mechanisms, such as vehicle crash, fire, or explosion
- The injury and harm that have resulted from exposure to the toxic hazardous substance

Most serious injuries and deaths from hazardous materials result from airway and breathing problems. Therefore, maintain the airway and, if the patient appears to be in distress, give oxygen at 12 to 15 L/min with a nonrebreathing mask. Monitor the patient's breathing at all times. If you see signs that indicate respiratory distress is increasing, then you may need to provide assisted ventilation with a bag-mask device and high-flow oxygen.

Treat the patient's injuries in the same way that you would treat any injury. There are few specific antidotes or treatments for exposure to most hazardous materials. Different people may respond differently to contact with the same hazardous material. Therefore, your treatment for the patient's exposure to the toxic substance should focus mainly on supportive care and initiating transport to the

hospital. If antidotes or other special treatments need to be initiated in the field, then medical control will order and relay them to the officer in charge of EMS operations at the scene. If any special treatment or advanced care, other than medications within the scope of practice of an AEMT and IV fluids, is needed, then paramedics or other advanced personnel will be sent to work with you in the treatment area.

Special Care

In some cases, before the decontamination area has been completely set up, the hazmat team will find one or two patients who need immediate treatment and transport without further delay if they are to survive. Even after the decontamination area is set up and functioning, some patients may have such respiratory distress or other critical condition that the time necessary for full decontamination may prove fatal. If additional delay for proper decontamination seems life threatening in nontoxic exposure situations, then it may be necessary to simply cut away all of the patient's clothing and do a rapid rinse to remove the majority of the contaminating matter before transport.

If you are treating and transporting a patient who has not been fully and properly decontaminated, then increase the amount of protective clothing you wear, including the use of SCBA. At the least, this should include two pairs of gloves, goggles or a face shield, a protective coat, respiratory protection, and a disposable fluid-impervious apron or similar outfit. Many hazmat teams carry light, easy-to-use, disposable, fluid-impervious protective suits for such a purpose. Remember, however, transporting a contaminated patient merely increases the scope of the event. The decision to transport even one patient with critical injuries rests with the IC, who bases the decision on recommendations made by the hazmat team.

To make decontaminating the ambulance easier, tape the cabinet doors shut. Any equipment kits, monitors, and other items that will not be used en route should be removed from the patient compartment and placed in the front of the ambulance or in outside compartments. Before loading the patient, turn on the power vent ceiling fan and patient compartment air-conditioning unit fan. Unless the weather is too severe, the windows in the driver's area and sliding side windows in

the patient compartment should also be partially opened to prevent creating a “closed box” inside the ambulance and to ensure it is properly ventilated for the safety of the patient and your team members.

When you leave the scene, inform the hospital that you are transporting a critically injured patient who has not been fully decontaminated at the scene. This will allow the hospital to prepare to receive the patient. Many EDs have decontamination facilities and trained personnel for such an event.

You may be diverted to a facility with these capabilities if the receiving hospital is not so equipped. On arrival, one AEMT enters the ED and, after giving hospital staff the report and advising them again of the incomplete decontamination, obtains directions before the patient is unloaded and brought in. If there are enough ambulances at a hazmat scene, then one ambulance may be isolated and used only to transport such patients. Remember, the ambulance needs to be decontaminated before transporting another patient.

YOU are the Provider **SUMMARY**

1. What are some hazards you may encounter with vehicle safety systems?

Some of the hazards that you may encounter at a crash scene include shock-absorbing bumpers that may become compressed and be under extreme pressures and could “explode,” injuring your knees and legs if you are standing in front of them. Airbags fill with a nonharmful gas when the devices deploy and are normally deflated on arrival of EMS; however, there may be instances where the airbag has not deployed prior to your arrival. An unexpected deployment has the potential to seriously injure anyone around the airbag. If you gain access to a patient via the front passenger seat and notice the airbag has not deployed, then you should exit the vehicle and seek alternative access. However, if alternative access is not possible, then use extreme caution and maintain a minimum clearance of 20 inches (50 cm) around passenger-side undeployed airbags, 10 inches (25 cm) around undeployed driver airbags, and 5 inches (13 cm) around side-impact undeployed airbags.

2. How should this vehicle be stabilized?

Unstable vehicles are typically stabilized by the fire department. However, in instances where the fire department is not yet at the scene, it may be necessary for you to stabilize the vehicle. Vehicles can be stabilized with a variety of jacks or cribbing, or any available material that may be present around the scene. Prior to attempting to gain access to a vehicle involved in a crash, ensure the vehicle is in “park” with the parking brake set and the ignition turned off. The battery should also be disconnected, negative side first, to minimize the possibility of sparks or fire.

3. What are the hazards that may present with hybrid electric vehicles?

Each type of electric drive vehicle has unique features, but one feature is common—the need for properly trained responders to disable the high-voltage battery pack to prevent electrical shock, fire, or explosion. In many alternative fuel vehicles, the batteries are not located in the engine compartment, but in other areas, such as in the trunk or under the seats. It is also important for you to remember that in hybrid electric vehicles, there may be more than one battery present.

4. What are the differences between simple access and complex access?

Simple access is an attempt to get to the patient as quickly and simply as possible. Typically, this is accomplished by unlocking doors or opening the windows. Simple hand tools, such as hammers, center punches, pry bars, come-alongs, and hacksaws, should be available on the ambulance for you to use. Complex access requires the use of specialized tools and training, typically provided by the local fire department with the jurisdictional requirements for extrication.

5. What should you do as the patient is being extricated from the vehicle?

During the extrication process, your input is essential so the patient’s injuries are considered as the rescue team plans a move that is quick and effective, but also protects the patient from further harm. Personal protection for both yourself and the patient is paramount. You and the patient should wear the appropriate personal protective equipment, as the situation permits. Finally, everyone inside must be protected from flying glass, metal, or other hazards during the extrication process.

YOU are the Provider SUMMARY *continued***6. How does rapid extrication differ from other methods of patient removal?**

Rapid extrication involves manually stabilizing the patient's head and, in most cases, moving the patient from a seated position in a vehicle to a supine position on a backboard, generally in 1 minute or less. The only resources and equipment needed are a cervical collar, a backboard, and adequate manpower. The main difference between the rapid extrication technique and other methods of patient removal is that it is fast and requires minimal preparation of the patient in the vehicle before the patient is removed.

7. What is the last phase of extrication?

The last phase of extrication is termination. Termination involves returning the emergency units to service. For rescue units, this process may be quite involved. All equipment used on the scene, including hydraulic, electrical, and hand tools, must be checked before reloading them on the apparatus. Whereas some tools require only generalized cleaning, others may need refueling and checking of the various fluid levels. You will also be required to check the ambulance thoroughly, replacing used supplies and conforming to cleaning needs required by bloodborne pathogen standards. Finally, rescue units and medical units will be required to complete all necessary reports.

EMS Patient Care Report (PCR)

Date: 10-3-21	Incident No.: 0103	Nature of Call: MVC	Location: 4 miles W on 464th Street.		
Dispatched: 0712	En Route: 0713	At Scene: 0725	Transport: N/A	At Hospital: N/A	In Service: 0755

Patient Information

Age: 27
Sex: M
Weight (in kg [lb]): 70 kg (156 lb)

Allergies: None
Medications: None
Past Medical History: None
Chief Complaint: Lower extremity paralysis

Vital Signs

Time: 0726	BP: Not obtained	Pulse: Not obtained	Respirations: 18	Spo₂: Not obtained
Time: 0730	BP: 110/76	Pulse: 105	Respirations: 20	Spo₂: 99%
Time: 0739	BP: 110/76	Pulse: 92	Respirations: 20	Spo₂: 99%

EMS Treatment (circle all that apply)

Oxygen @ <u>15</u> L/min via (circle one): NC (NRM) Bag-mask device		Assisted Ventilation	Airway Adjunct	CPR
Defibrillation	Bleeding Control	Bandaging: Spinal motion restriction	Splinting	Other: Extrication

Narrative

EMS dispatched to above location for MVC. On arrival, incident command states patient is heavily entrapped from rollover crash. Vehicle is found sitting on roof, massive damage noted to both sides of smaller passenger car. Extrication supervisor states vehicle is hybrid electric vehicle and all batteries have been disconnected. He further states the patient is pinned by his legs, extrication should take 15 to 20 minutes, and one of his firefighters is in the backseat immobilizing the patient's spine. Proceeded to passenger side of vehicle to patient. Patient is alert and oriented x 4, ABCs intact, complaining of lack of sensation to his legs. Discussed helicopter request with IC, who agreed. Dispatch contacted, requested helicopter response. Landing zone established by fire department personnel. Nonrebreathing mask applied at 15 L/min. At 0739, access to the patient via driver's side is secured. Cervical collar applied, and patient placed on long backboard and secured. Patient placed on stretcher, and into back of ambulance. 14-gauge IV established to patient's left wrist, TKO. On arrival of flight crew, report given to flight paramedic. Patient loaded into helicopter, EMS returned to service.

End of report

Prep Kit

Ready for Review

- Safety during special rescue situations such as vehicle extrication or trench rescue begins with the proper mindset and the proper personal protective equipment.
- During all phases of rescue, your primary concern is safety, and your primary role is to provide emergency medical care and prevent further injury to the patient.
- The 10 phases of extrication are:
 1. Preparation
 2. En route to the scene
 3. Arrival and scene size-up
 4. Hazard control
 5. Support operations
 6. Gaining access
 7. Emergency medical care
 8. Removal of the patient
 9. Transfer of the patient
 10. Termination
- During scene size-up, while you are paying attention to potential hazards, identify the safest, most efficient way to access the patient. Determine what, if any, additional resources will be needed.
- A variety of hazards may be present at the extrication scene. Potential hazards include downed electrical lines, hazardous materials, traffic, bystanders, and other vehicles, including electric drive vehicle with high-voltage batteries.
- Do not approach an electric or alternative fuel vehicle without proper turnout gear, including self-contained breathing apparatus. Keep in mind a fire from methanol or ethanol may be hard to see.
- Vehicle safety systems, such as shock-absorbing bumpers and airbags, protect your patients but also have the potential to injure rescuers.
- You and the ambulance should remain outside of the danger zone, which is an area where people can be exposed to sharp metal edges, broken glass, toxic substances, radiation, or ignition or explosion of hazardous materials.
- A critical phase of extrication is gaining access to the patient. Do not attempt to gain access to the patient until you are sure the scene is safe and that any hazards have been identified and either properly controlled or eliminated. Ensure the patient remains safe during extrication, and extrication efforts must be well coordinated.
- Unless there is immediate danger, during a vehicle extrication, perform a primary assessment while the patient is still in the vehicle. Immobilize the cervical spine before moving the patient from the vehicle.
- If a special rescue team is needed, inform the dispatcher.
- When a scene calls for a search or for specialized rescue, you may have to call for a technical rescue group, or you may find one already at work when you arrive. Your interaction and cooperation with this group, and with an IC when one has been designated, are important to a smooth rescue.
- You will be involved to some degree in the logistics of patient movement and patient care.
- Tactical situations are best handled directly by special weapons and tactics teams. Your role will often largely consist of remaining out of danger, cooperating with the IC, and remaining ready to care for any patients that are brought to you.
- You may be summoned to a lost person search and rescue. In this situation, your role is to stand by at the command post or the staging area until the lost person or people have been found.
- Trench rescue refers to cave-ins and collapses. Collapses usually involve large areas of falling dirt. The risk of a secondary collapse during

the rescue operation is of concern to rescue personnel and to the AEMTs. Ensure vehicles are parked at least 500 feet (152 m) from the scene and are turned off.

- At structure fires, determine whether a special route is necessary, ask the IC where the ambulance should be parked, and ensure the ambulance will not block or hinder other arriving equipment or become blocked in by other equipment or hose lines. Also, the ambulance should leave the scene only if transporting a patient or if the IC has released it.
- When you arrive at the scene of a hazmat incident, first step back and assess the situation. This can be very stressful, particularly if you see a patient.
- The presence of labels, placards, and other markings on buildings, packages, boxes, and containers can enable you to identify a released substance.
 - The US DOT hazardous materials marking system is used when materials are being transported from one location to another.
 - The NFPA 704 hazard identification system is designed for fixed-facility use.
- Valuable resources for determining what the hazardous material is and what you should do are the *ERG*, safety data sheets, and the Chemical Transportation Emergency Center.
- As an EMS provider wearing the lowest level of protection (level D), you will remain in the cold zone, or the safe area.

Vital Vocabulary

access Gaining entry to an enclosed area and reaching a patient.

active shooter A gunman who has begun to fire on people and is still at large.

alternative fuel vehicle A vehicle that uses anything other than a petroleum-based motor fuel (gasoline or diesel) to propel a motorized vehicle.

bills of lading The shipping papers used for transport of chemicals over roads and highways; also referred to as freight bills.

bulk storage containers Any container other than nonbulk storage containers, such as fixed tanks, highway cargo tanks, rail tank cars, totes, and intermodal tanks. These are typically found in manufacturing facilities and are often surrounded by a secondary containment system to help control an accidental release.

carboys Glass, plastic, or steel containers, ranging in volume from 5 to 15 gallons (19 to 57 L).

Chemical Transportation Emergency Center (CHEMTREC) An agency that assists emergency responders in identifying and handling hazardous materials incidents.

cold zone A safe area at a hazardous materials incident for the agencies involved in the

operations. The incident commander, the command post, EMS providers, and other support functions necessary to control the incident should be located in this zone. Also referred to as the clean zone or the support zone.

complex access Entry that requires special tools and training and includes the use of force.

concealment The use of objects to limit a person's visibility of you.

container Any vessel or receptacle that holds material, including storage vessels, pipelines, and packaging.

control zones Areas at a hazardous materials incident that are designated as hot, warm, or cold, based on safety issues and the degree of hazard found there.

cover The tactical use of an impenetrable barrier for protection.

cylinders Portable, compressed-gas containers used to hold liquids and gases such as nitrogen, argon, helium, and oxygen. They have a range of sizes and internal pressures.

danger zone An area where people can be exposed to hazards such as electric wires, sharp metal edges, broken glass, toxic substances,

radiation, or ignition or explosion of hazardous materials.

decontamination The process of removing or neutralizing and properly disposing of hazardous materials from equipment, patients, and responders.

decontamination area The designated area in a hazardous materials incident where all patients and responders must be decontaminated before going to another area.

drums Barrel-like containers used to store a wide variety of substances, including food-grade materials, corrosives, flammable liquids, and grease. May be constructed of low-carbon steel, polyethylene, cardboard, stainless steel, nickel, or other materials.

Emergency Response Guidebook (ERG) A preliminary action guide for first responders operating at a hazardous materials incident in coordination with the US Department of Transportation's (DOT) labels and placards marking system. Jointly developed by the DOT, the Secretariat of Communications and Transportation of Mexico, and Transport Canada.

entrapment To be caught (trapped) within a vehicle, room, or other confined space with no way out, or to have a limb or other body part trapped.

extrication Removal of a patient from entrapment or a dangerous situation or position, such as removal from a wrecked vehicle, industrial incident, or building collapse.

freight bills The shipping papers used for transport of chemicals along roads and highways; also referred to as bills of lading.

hazardous materials Any substances that are toxic, poisonous, radioactive, flammable, or explosive and cause injury or death with exposure.

hazardous materials (hazmat) incident An incident in which a hazardous material is no longer properly contained and isolated.

hot zone The area immediately surrounding a hazardous materials spill or incident site that endangers life and health. All personnel working in this zone must wear appropriate protective clothing and equipment. Entry requires approval by the incident commander or other designated officer.

incident commander (IC) The overall leader of the incident command system to whom commanders or leaders of incident command system divisions report.

intermodal tanks Shipping and storage vessels that can be either pressurized or nonpressurized.

Level A protection Personal protective equipment used for protection against vapors, gases, mists, and even dusts. The highest level of protection, it is an encapsulating suit that includes a self-contained breathing apparatus.

Level B protection Personal protective equipment used when the type and atmospheric concentration of substances require a high level of respiratory protection but less skin protection. The kinds of gloves and boots worn depend on the identified chemical.

Level C protection Personal protective equipment used when the type of airborne substance is known, the concentration is measured, the criteria for using an air-purifying respirator are met, and skin and eye exposure is unlikely. This ensemble consists of standard work clothing with the addition of chemical-protective clothing, chemically resistant gloves, and a form of respiratory protection.

Level D protection Personal protective equipment used when the atmosphere contains no known hazard, and work functions preclude splashes, immersion, or the potential for unexpected inhalation of or contact with hazardous levels of chemicals. This is the lowest level of protection and is primarily a work uniform that includes coveralls.

nonbulk storage vessels Any container other than bulk storage containers such as drums, bags, compressed gas cylinders, and cryogenic containers. These hold commonly used commercial and industrial chemicals such as solvents, industrial cleaners, and compounds.

personal protective equipment (PPE) levels Indicate the amount and type of protective equipment that an individual needs to avoid injury during contact with a hazardous material.

placards Signage required to be placed on all four sides of highway transport vehicles, railroad tank cars, and other forms of hazardous materials transportation; the sign identifies the hazardous contents of the vehicle, using a standardization system with 10¾-inch (27-cm) diamond-shaped indicators.

safe zone An area of protection providing safety from the danger zone (hot zone).

safety data sheet (SDS) A form provided by manufacturers and compounders (blenders) of chemicals, containing information about chemical composition, physical and chemical properties, health and safety hazards, emergency response, and waste disposal of a specific material; this term has replaced material safety data sheet.

secondary containment An engineered method to control spilled or released product if the main containment vessel fails.

self-contained breathing apparatus (SCBA) Respirator with independent air supply used by firefighters to enter toxic and otherwise dangerous atmospheres.

simple access Access that is easily achieved without the use of tools or force.

situational awareness Knowledge and understanding of one's surroundings and the ability to recognize potential risks to the safety of the patient or the emergency medical services team.

size-up The ongoing process of information gathering and scene evaluation to determine appropriate strategies and tactics to manage an emergency.

special weapons and tactics (SWAT) team A specialized law enforcement tactical unit.

tactical medicine Emergency medical care provided by specially trained emergency medical responders, advanced emergency medical technicians, paramedics, nurses, and even physicians during a tactical situation.

tactical situation A hostage, robbery, or other situation in which armed conflict is threatened or shots have been fired and the threat of violence remains.

technical rescue group A team of emergency responders from one or more departments in a region who are trained and on call for certain types of technical rescue.

technical rescue situation A rescue that requires special technical skills and equipment in one of many specialized rescue areas, such as technical rope rescue, cave rescue, and dive rescue.

warm zone The area located between the hot zone and the cold zone at a hazardous materials incident. The decontamination corridor is located in the warm zone.

Chapter 41

Incident Management

NATIONAL EMS EDUCATION STANDARD COMPETENCIES

EMS Operations

Knowledge of operational roles and responsibilities to ensure patient, public, and personnel safety.

Incident Management

- Establish and work within the incident management system. (p 1968)

Multiple Casualty Incidents

- Triage principles (pp 1978–1979)
- Resource management (p 1968)
- Triage (pp 1978–1984)
 - Performing (pp 1978–1979)
 - Re-triage (p 1979)
 - Destination decisions (pp 1983–1984)
 - Posttraumatic and cumulative stress (p 1977)

KNOWLEDGE OBJECTIVES

1. Describe the National Incident Management System (NIMS) and its major components. (p 1968)
2. Describe the purpose of the incident command system (ICS) and its organizational structure. (pp 1969–1970)
3. Explain the role of emergency medical services (EMS) response within the ICS. (pp 1973–1974)
4. Describe how the ICS assists EMS in ensuring both personal safety and the safety of bystanders, health care professionals, and patients during an emergency. (p 1972)
5. Describe your role as an advanced emergency medical technician (AEMT) in establishing command under the ICS. (pp 1973–1974)
6. Describe the purpose of medical incident command within the ICS and its organizational structure. (pp 1975–1977)
7. Describe the specific conditions that would define a situation as a mass-casualty incident (MCI); include examples. (pp 1977–1978)
8. Describe what occurs during primary and secondary triage, how the four triage categories are assigned to patients on the scene, and how destination decisions regarding triaged patients are made. (pp 1979–1981, 1983–1984)
9. Describe how to perform the START and JumpSTART triage methods. (pp 1981–1983)
10. Explain how a disaster differs from an MCI. (pp 1984–1985)
11. Describe the role of the AEMT during a disaster operation. (p 1985)

SKILLS OBJECTIVES

1. Demonstrate how to perform triage based on a fictitious scenario that involves a mass-casualty incident. (pp 1977–1979)

Introduction

Some of the most challenging situations you will encounter are disasters and **mass-casualty incidents (MCIs)**. In this text, a **disaster** refers to any situation that overwhelms your resources. For example, you may find many patients, a lack of specialized equipment, and/or inadequate help. An incident with two critical patients can constitute a disaster if only one emergency medical services (EMS) unit is available to respond. Bus or train crashes are obvious examples of MCIs.

A **multiple-casualty incident** refers to any situation with more than one patient, but which will not overwhelm available resources. There is no set numerical cutoff at which a multiple-casualty incident becomes a mass-casualty incident. Rather, a mass-casualty incident is declared when the number of patients and severity of injuries presenting at a given time or place suggest that available community resources could be overwhelmed, therefore requiring assistance per mutual aid response, discussed later in this chapter. For the purposes of this text, the term mass-casualty incident (MCI) is used throughout.

When you respond to any incident with a large number of patients, you must use a systematic approach to manage the incident most efficiently. By learning to use the principles of the incident command system (ICS), you will be able to make the best use of your resources. As an advanced emergency medical technician (AEMT), you will typically be assigned to work within the EMS/medical branch under an ICS, but you may be asked to function in other areas, which will be discussed later in this chapter. The National Incident Management System (NIMS) was developed to promote more efficient coordination among emergency responders at the regional, state, and national levels. To reduce on-scene problems and to increase your efficiency, you need a solid understanding of the basics of the

NIMS. You may also access training courses through the Federal Emergency Management System (FEMA) website.¹ These courses include ICS-100, Introduction to the Incident Command System, and FEMA IS-700, National Incident Management System, An Introduction.

National Incident Management System

In 2004, the Department of Homeland Security implemented the **National Incident Management System (NIMS)**. The NIMS provides a consistent, nationwide approach to incident management, enabling federal, state, and local governments, private-sector and nongovernmental organizations, and all other organizations who assume a role in emergency management to work together effectively and efficiently. The NIMS is used to prepare for, prevent, respond to, and recover from domestic incidents, regardless of cause, size, or complexity, including acts of catastrophic terrorism and hazardous materials (hazmat) incidents.

Two important underlying principles of the NIMS are flexibility and standardization. The organizational structure must be flexible enough to be rapidly adapted for use in any situation. The NIMS provides standardization in terminology, resource classification, personnel training, certification, and more. Another important feature of the NIMS is the concept of interoperability, which refers to the ability of agencies of different types or from different jurisdictions to communicate with each other. Major incidents require the involvement and coordination of multiple jurisdictions, agencies, and emergency response disciplines.

The NIMS is composed of these four components²:

1. Fundamentals and Concepts of NIMS
2. Resource Management
3. Command and Coordination
4. Communications and Information Management

As an AEMT, your role falls within the Command and Coordination component of NIMS. The other components are vital parts of NIMS, but your role as an AEMT is not as directly related to these functions. Additional information on NIMS is available at the FEMA website.

Words of Wisdom

A multiple-vehicle pileup on an interstate may constitute a small-scale MCI. The series of terrorist attacks on September 11, 2001 are examples of MCIs on a much larger scale.

Incident Command System

The **incident command system (ICS)** is an important component of the NIMS that falls under Command and Coordination. Developed in the 1970s and pioneered by the fire service, the ICS is a standardized, on-scene emergency management model specifically designed to provide for an integrated organizational structure that reflects the complexity and demands of an incident.³ (Some agencies refer to the incident command system as the incident management system.) The purpose of the ICS is to enhance command, control, and communication abilities; ensure responder and public safety; achieve incident management goals; ensure the efficient use of resources; and treat patients during an emergency.

Words of Wisdom

Using the ICS gives you a modular organizational structure that can be applied to all hazards. ICS is activated for incidents ranging from a single vehicle crash with one patient to a natural gas pipeline explosion involving multiple communities and multiple patients.

The ICS is designed to avoid duplication of effort and **freelancing**, in which individual units or different organizations make independent and often inefficient decisions about the next appropriate action. Follow your local standard operating procedures for establishing the ICS.

One of the organizing principles of the ICS is limiting the **span of control** of any one individual. This principle refers to keeping the supervisor/worker ratio at one supervisor for three to seven workers. A supervisor to whom more than seven people are reporting is exceeding an effective span of control and needs to divide tasks and delegate the supervision of some tasks to another person.

The organizational levels may include sections, branches, divisions, and groups as follows (**FIGURE 41-1**):

- *Sections* are responsible for a major functional area such as finance, logistics, planning, or operations.
- *Branches* are managed by the branch director and may be functional or geographic in nature. Branches tend to be established when span of control is a problem, such as at larger incidents, where more oversight may be needed. Branches are in charge of activity

FIGURE 41-1 The incident command system organizational structure may include sections, branches, divisions, and groups.

YOU are the Provider

Part 1

As you are preparing to sit down for lunch with the rest of the firefighters from your station, the radio squawks, "Engines 21-1, 21-2, 21-4, Towers 21-1, 24-1, Tender 33-5, Heavy Rescue 22-3, Medics 21-1, 22-1, and Chief 21 respond to 152 Main Street for a building collapse. Multiple casualties reported. Time out 1214." Everyone looks at each other, then proceeds expeditiously to their apparatus. As you advise dispatch that your unit is responding, Chief 21 advises that he is at the scene of a commercial office building collapse with multiple injuries. Chief 21 will be assuming command with the command post located at the corner of Main Street and 1st Avenue. He also advises that the staging area will be located at 1st Avenue and 1st Street.

1. What is the NIMS?
2. Why is NIMS helpful to all emergency responders?

directly related to the section (eg, fire, law enforcement, EMS, operations, etc).

- *Divisions* and *groups* serve to align resources and/or crews under one supervisor. Divisions usually refer to crews working in the same geographic area. Groups usually refer to crews working in the same functional area, but possibly in different locations.

In general, the larger the incident, the more divisions there will be. A small incident may require support only from the fire department, EMS, and law enforcement. By contrast, a large incident will require many agencies to work together.

In some regions, emergency operations centers may exist. The centers are usually operated by the city, state, or federal government. These centers will usually be activated only in a large catastrophic event that may go on for days, involves hundreds of patients, and taxes the entire system.

Emergency responders who assume a role in incident management should use the ICS. Find out from your service if one exists, who is in charge, how it is activated, and what your expected role will be.

Incident Command System Roles and Responsibilities

Many roles are defined in the ICS. The general staff includes **command**, finance and administration, logistics, operations, and planning personnel. It is important for you to understand the specific duties of each section and how they work to coordinate the response. Command functions may include a public information officer, safety officer, and liaison officer.

Command

The **incident commander (IC)** is the person in charge of the overall incident. The IC will assess the incident, establish the strategic objectives and priorities, and develop a plan to manage the incident (**FIGURE 41-2**). The number of command duties the IC takes on often varies by the size of the incident. Small incidents often mean the IC will do it all. In an incident of medium size or complexity, the IC may delegate some functions but retain others. For example, at a motor vehicle crash with multiple patients, the IC may designate a safety officer but maintain responsibility for the other command

FIGURE 41-2 The incident commander at a mass-casualty incident oversees the incident and develops a plan for the response.

© Helen H. Richardson/MediaNews Group/The Denver Post/Getty Images.

functions. In a complex situation, the IC may appoint team members to all of the command roles.

A large-scale incident, such as a hazmat spill, requires a multiagency or multijurisdiction response and a **unified command system**. In this case, plans are drawn up in advance by all cooperating agencies that assume a shared responsibility for decision making. The response plan should designate the lead and support agencies in several kinds of incidents. (For example, the hazmat team will take the lead in a chemical leak; however, the medical team might take the lead in a multivehicle crash.) Agencies that share a border should train often with each other to ensure that a unified command system will function well and that communication among the responders is well established before a real incident occurs.

A **single command system** is one in which one person is in charge, even if multiple agencies respond. It is generally used during incidents in which one agency has most of the responsibility for incident management. Ideally, it is used for short-duration, limited incidents that require the services of a single agency.

Your IC should be on or near the scene, where it is easy to communicate with all emergency responders operating at the scene. It is important that you know who the IC is, how to communicate with this person, and where the **command post** is located. If the incident is very large, then you will report to a supervisor working under the IC. (Remember the rule of span of control.) To make the IC easily identifiable, some type of garment is

worn, such as a brightly colored vest labeled with the word COMMAND. If the command post is set up in a vehicle, then it should be well marked, and you should know its location. Make sure that your supervisor or the IC knows of any plans or operations before they are initiated.

Communication is particularly important if a transfer of command takes place. Because an incident can rapidly change in size and complexity, an IC may turn over command to someone with more experience in a critical area. This change, or transfer of command, must take place in an orderly manner and, if possible, face-to-face. In extreme situations, it could be done by phone, radio, or email, although these methods are not recommended. Your agency should have standard operating procedures that govern the transfer of command. Make certain to follow the standard operating procedures. When an incident draws to a close and the command structure is no longer necessary, a **termination of command** should take place. Your agency should implement **demobilization** procedures as the situation deescalates or comes to an end. Demobilization is the process of directing responders to return to their facilities when their work at an incident has finished.

Finance and Administration

The **finance and administration** section is responsible for documenting all expenditures at an incident, including the expenditures for materials and supplies, and documenting personnel hours. Finance and administration personnel are not usually needed at smaller incidents, but at larger incidents they are necessary. Ultimately, the information gathered is reported at meetings of the general staff. Responding agencies and organizations may be eligible for some types of reimbursement after the incident, and efficient finance and administration personnel will help your agency to succeed in the reimbursement process. Finance and administration personnel should be trained in the process of assessing expenditures with an eye to reimbursement long before an actual incident.

The various functions within the finance and administration section include (1) the time unit, (2) the procurement unit, (3) the compensation/claims unit, and (4) the cost unit. The time unit is responsible for ensuring the daily recording of personnel time and equipment use. The procurement

unit deals with all matters concerning vendor contracts. The compensation and claims unit has two major purposes: dealing with claims as a result of the incident and injury compensation. Finally, the cost unit is responsible for collecting, analyzing, and reporting the costs related to an incident.

Logistics

The **logistics** section is responsible for communications equipment, facilities, food and water, fuel, lighting, and medical equipment and supplies for patients and emergency responders. Local standard operating procedures will list the medical equipment needed for the incident, depending on the type of incident. Logistics personnel are trained to find food, shelter, and health care for you and the other responders at the scene. In a large incident, it is often necessary for many people to handle logistics, even though only one person (section chief) will report to the IC.

Operations

At a very large or complex incident, the IC will appoint an **operations** section chief, who is responsible for managing the tactical operations usually handled by the IC on routine EMS calls. This arrangement frees the IC to coordinate with other agencies and the media, engage in strategic planning, and ensure that logistics are functioning effectively. The operations section chief will supervise the people working at the scene of the incident, who will be assigned to branches, divisions, and groups. Operations personnel often have experience in management within EMS.

Planning

The **planning** section solves problems as they arise during the incident. Planners analyze, investigate, and obtain data; develop objectives for the incident; select a strategy to meet the objectives; and determine the resources needed to execute a plan.⁴ They need to work closely with the operations, finance, and, especially, logistics sections. Planners can and should call on technical experts to help with the planning process. They document their decisions and what they learned from the incident and also set out a course for demobilizing the response when necessary.

Another important function of the planning section is the development of an **incident action plan**, which is the central tool for planning during a response to a disaster. The incident action plan is prepared by the planning section chief with input from the appropriate sections and units of the incident command team. It should be written at the outset of the response and revised continually throughout the response. For smaller, readily controlled incidents, a written plan may not be necessary and the IC may deliver the plan verbally. Larger, more complex incidents will require a formal incident action plan to coordinate activities. The level of detail required in an incident action plan will vary according to the size and complexity of the response.

Words of Wisdom

The size and scale of the incident will dictate the number of roles assigned by the IC.

Command Staff

Three important positions that help the general staff (all staff described previously) and the IC are the safety officer, the public information officer, and the liaison officer. The **safety officer** monitors the scene for conditions or operations that may present a hazard to responders and patients. The safety officer may need to work with environmental health and hazmat specialists. The importance of the safety officer cannot be underestimated; this person has the authority to stop an emergency operation whenever a responder is in danger. A safety officer should remove hazards to EMS personnel and patients before the hazards cause injury.

The **public information officer (PIO)** provides the public and media with clear and understandable information. Wise PIOs position their headquarters well away from the incident command post and, most important, away from the incident, to minimize distractions. Also, the PIO must keep the media safe and from becoming part of the incident. The designated PIO may work in cooperation with PIOs from other agencies in a **joint information center (JIC)**. In some circumstances, the PIO/JIC may be responsible for distributing a message designed to help a situation, prevent panic, and provide evacuation directions.

The **liaison officer** relays information and concerns among command, the general staff, and other agencies. If an agency is not represented in the command structure, then questions and input should be given through the liaison officer.

Communications and Information Management

Communications has historically been the weak point at most major incidents. To minimize the effects of communications problems, it is recommended that communications be integrated so that all agencies involved can communicate quickly and effortlessly via radios. Communications allow for accountability throughout the incident, as well as instant communications between recipients. As always, and more so during a large incident, it is important to maintain professionalism on all radio communications, and remember to communicate clearly and concisely using clear text (no 10-codes).

Mobilization and Deployment

When an incident has been declared and the need for additional resources has been identified, a

YOU are the Provider

Part 2

You arrive at the staging area shortly after a lieutenant from Engine 21-4 has been designated as the staging supervisor. The IC directs your unit to assume the role of triage, as the rescue crews bring the patients into the triage area. As soon as you establish a triage area, you are immediately bombarded with seven patients.

3. What is the function of the staging supervisor?
4. What is the function of the triage supervisor?

request is made for additional resources. After a request is made, these resources are mobilized and deployed to the scene. To minimize the potential for freelancing, wait until the request is made before you depart for the scene.

Check-in at the Incident

On arrival at an incident, first check in with the IC at the command post, base, staging area, or other location designated by the IC. If the incident is large in size or complexity, then remember you will be assigned to a supervisor working under the IC.⁵ Check-in allows for personnel tracking throughout the incident and also ensures that costs, pay, and reimbursement can be calculated accurately.

Initial Incident Briefing

After the check-in process is complete, report to your supervisor for an initial briefing that will allow you to get information regarding the incident, as well as your specific job functions and responsibilities.

Incident Record Keeping

Record keeping is important for financial reasons and for documentation purposes. If a large piece of equipment becomes inoperable, then it may be possible for the agency to be reimbursed for replacement costs. Record keeping also allows for tracking of time spent on the incident for reimbursement purposes.

Accountability

Because of the large number of responders at a large incident, accountability is important. Accountability means keeping your supervisor advised of your location, actions, and completed tasks. It also includes advising your supervisor of the tasks that you have been unable to complete and what tools you need to complete them.

Incident Demobilization

After the incident has been stabilized and all of the hazards mitigated, the IC will determine which resources are needed or not needed and when to begin demobilization. This process allows for a prompt return of resources to their parent organizations to be placed back in service.

EMS Response Within the Incident Command System Preparedness

Preparedness involves the decisions made and basic planning done before an incident occurs. Every state is at risk for natural disasters, such as hurricanes, tornadoes, earthquakes, and wildfires. Therefore, preparedness in a given area involves anticipating the most likely natural disasters for the area, among other disasters.

Your EMS agency should have written disaster plans that you are regularly trained to carry out. A copy of the disaster plan should be kept in each EMS vehicle. EMS facilities should have disaster supplies for at least a 72-hour period of self-sufficiency. Your EMS service should have **mutual aid response** agreements with neighboring EMS systems to respond when local resources are insufficient to handle response. All groups with mutual aid response agreements should practice using the plans frequently. EMS systems should share a list of resources with each other so they will know early on what they can access. Also, your local EMS systems should develop an assistance program for the families of EMS providers. If EMS providers have concerns about their families during a disaster, then their effectiveness on the job could be diminished.

Safety

You should have a personal disaster plan for your family. Families need to be prepared and know what to expect should you be required to respond to a disaster. You should also be up-to-date on immunizations for influenza, hepatitis A and B, and tetanus.

Scene Size-up

Remember that scene size-up starts with dispatch. If dispatch information indicates a possible unsafe scene, then stay away from the scene or get only close enough to make an assessment without putting yourself in harm's way. When you arrive first on the scene of an incident, you will make an initial assessment and some preliminary decisions.

The scene size-up will be driven by three basic questions that you must ask yourself:

- *What do I have?*
- *What resources do I need?*
- *What do I need to do?*

These questions have a symbiotic relationship. The answer from one helps answer the others, and each answer represents a piece to the puzzle. Work as a team when you answer these questions because overlooking just one safety issue early on can start a chain reaction of problems.

What Do I Have?

Start with scene safety. First, assess the scene for hazards. Warn all other responders about hazmat, fuel spills, electrical hazards, or other safety concerns as soon as possible. Confirm the incident location.

Establish whether the incident is open or closed. An **open incident** is one that is not yet contained; there may be patients who have yet to be located and the situation may be ongoing, producing yet more patients. A **closed incident** is one that is contained and in which all casualties are accounted for. However, as with any situation, a closed incident may quickly become an open incident as situations change.

Estimate the number of casualties. Immediately provide a brief incident report to dispatch. An example of such a report would be: “AEMT unit number one arriving on scene, multiple vehicles involved, full road blockage, no apparent hazards at this time, AEMT unit number one is assuming command.”

What Resources Do I Need?

Decide what resources are needed. You may need more EMS responders, ambulances, or other forms of transportation. If extrication is required, then a rescue unit and fire department response may be needed. If hazardous materials are present, then request a hazmat team immediately. Many large EMS systems deploy specialized MCI units or mobile emergency room vehicles that are able to treat dozens of patients on the scene (**FIGURE 41-3**).

What Do I Need to Do?

Keep the following priorities in mind:

- Safety
- Incident stabilization
- Preservation of property and the environment

FIGURE 41-3 This mobile emergency room is staffed by EMTs, AEMTs, paramedics, and physicians who are able to provide advanced life support to multiple patients simultaneously on the scene of a mass-casualty incident.

© Jones & Bartlett Learning. Courtesy of MIEMSS.

You need to consider these priorities in the order they are given. Safety is paramount. Safety includes your life, your partner's life, and other responders' lives. Then, consider the safety of the patient and any bystanders. This concept will be difficult for anyone dedicated to saving lives, but it is important to put yourself and your partner first. You have the skills, and bystanders usually do not; the situation can worsen if you become a patient yourself. Often, if a responder is injured, then other responders will focus on “their own,” removing available resources from the incident.

You may have to initially work to isolate or stabilize the incident before providing emergency medical care to injured people; this is another difficult concept for all emergency workers. Remember, you cannot help the injured if the scene is unstable. An unstable scene can lead to an injured AEMT.

Establishing Command

After you have performed a good scene size-up and answered the three basic questions, command should be established by the most senior official, notification to other responders should go out, and necessary resources should be requested. A command system ensures that resources are effectively and efficiently coordinated. Command must be established early, preferably by the most experienced public safety official to arrive first. These officials may include police, fire, or EMS personnel.

Communications

As discussed earlier, communications is often the key challenge at an MCI or a disaster. The infrastructure may be damaged, or communications capabilities may be overwhelmed. If possible, then, use face-to-face communication to limit radio traffic. Some organizations responding to a disaster might not know how to use a radio. If you communicate via radio, then do not use 10-codes or signals. Most communications problems should be worked out before a disaster happens by designating channels strictly for command during a disaster. Whatever form of communications equipment is used, it must be reliable, durable, and field-tested. Be sure that backups are in place if the primary communications system does not work. Some regions have mobile self-contained communications centers, whereas others use local radio groups such as ham radio operators to assist with communications. Most important, your plan should include a “Plan B” in case of communications failure.

Medical Incident Command

What has traditionally been referred to as **medical incident command** is more commonly known as the medical (or EMS) branch of the ICS (**FIGURE 41-4**). At incidents that have a significant medical factor, the IC should appoint someone as the medical branch director. This person will supervise the primary roles of the medical branch—**triage**, treatment, and transport of injured people. Triage simply means *to sort* your patients based on the severity of their injuries (discussed later in this chapter). The medical branch director should help ensure that EMS units responding to the scene are working within the ICS, each medical group receives a clear assignment before beginning work at the scene, and personnel remain with their vehicles in the staging area until they are assigned their duties. Depending on the scale of the incident, EMS may be a branch within the operations section or may fall under the logistics section as a unit.

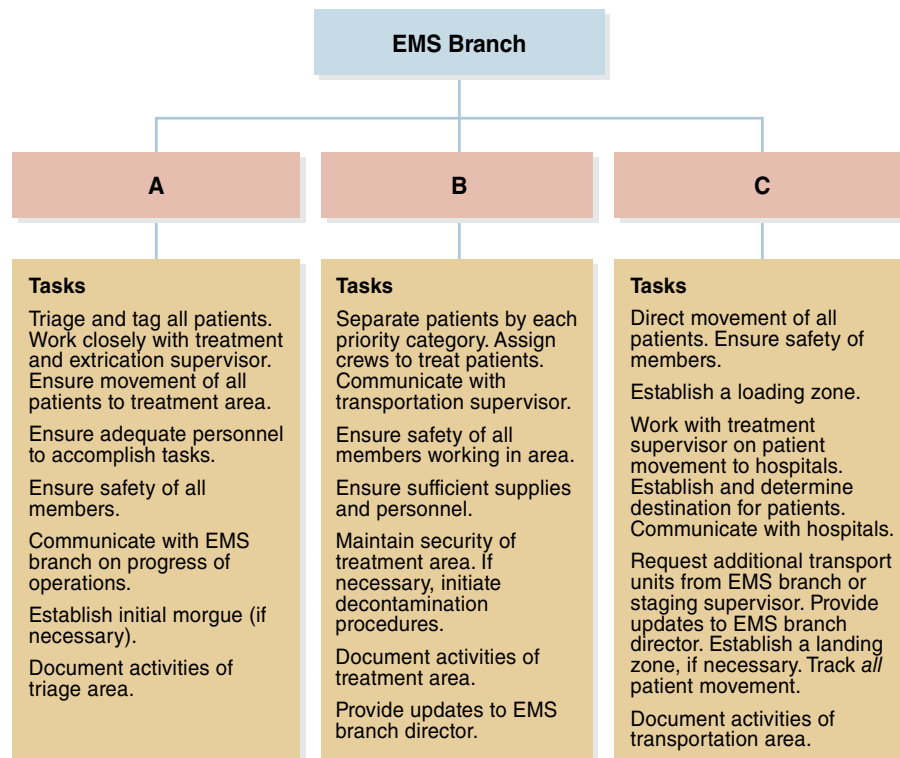

FIGURE 41-4 Components of the medical branch within the incident command system.

Triage Supervisor

The **triage supervisor** is ultimately in charge of counting and prioritizing patients. During large incidents, many triage personnel may be needed (**FIGURE 41-5**). The primary duty of the triage group is to ensure that every patient receives an initial assessment of their condition. AEMTs doing triage will help move patients to the appropriate treatment sector. One of the most difficult parts of being a triage supervisor is that you must not begin treatment until all patients are triaged, or you will compromise your triage efforts.

Treatment Supervisor

The **treatment supervisor** will locate and set up the **treatment area** with a tier for each priority of patient. The treatment supervisor ensures that secondary triage of patients is performed and that adequate patient care is given as resources allow. The treatment supervisor also assists with moving patients to the **transportation area**. While supervising the responders, the treatment supervisor must communicate with the medical branch director to request sufficient supplies, including bandages, burn supplies, airway and respiratory supplies, and patient packaging equipment.

FIGURE 41-5 Mass-casualty incidents require triage.

© David Crigger, Bristol Herald Courier/AP Photo.

Transportation Supervisor

The key role of the **transportation supervisor** is to coordinate the transportation and distribution of patients to appropriate receiving hospitals and help to ensure that hospitals do not become overwhelmed by a patient surge. The transportation supervisor also coordinates with the incident commander to help ensure that enough personnel and ambulances are in the staging area or have been requested. Some regions may plan for a designated hospital within a region to perform the coordination between hospitals on destination decisions. A disaster or an MCI typically disrupts the everyday functioning of the regional trauma system, so effective coordination is needed. The transportation supervisor documents and tracks the number of transport vehicles, patients transported, and the facility destination of each vehicle and patient.

Staging Supervisor

A **staging supervisor** is assigned when an MCI or a disaster requires a multivehicle or multiagency response. Emergency vehicles must have permission from the staging supervisor to enter the scene of the MCI and should drive only in the directed area. The staging area should be established away from the scene so that the parked vehicles are not in the way. The staging supervisor locates an area to stage equipment and responders, tracks unit arrivals, and releases vehicles and supplies when ordered by incident command. The staging supervisor plans for efficient access to and exit from the disaster site and prevents traffic congestion among responding vehicles.

Physicians on Scene

In an MCI or disaster, some areas have plans in place for physicians to be sent to the scene. Sometimes, even without a plan, the enormity of the situation may require physicians to be on scene. Emergency physicians, especially, will have the ability to make difficult triage decisions. They also provide secondary triage decisions in the treatment area, deciding which priority patients are to be transported first. Physicians can provide on-scene medical direction for AEMTs, and they can provide medical care in the treatment area as appropriate.

Rehabilitation Supervisor

In disasters or MCIs that will last for extended periods, a rehabilitation section for the responders should be established. The **rehabilitation supervisor** establishes an area that provides protection for responders from the elements and the situation. The **rehabilitation area** should be located away from exhaust fumes and crowds (especially members of the media) and out of view of the scene itself. The rehabilitation area is where a responder's needs for rest, fluids, food, and protection from the elements are met. The rehabilitation supervisor must also monitor responders for signs of physical and/or emotional stress, including posttraumatic stress disorder (a delayed stress reaction to a prior incident) or cumulative stress (prolonged or excessive stress). These signs may include fatigue, altered thinking patterns, and complete collapse. Remember that all EMS personnel must be aware of signs of stress. Consider taking advantage of critical incident stress debriefing (CISD) or critical incident stress management (CISM) opportunities after an incident if you feel they may be valuable. Chapter 2, *Workforce Safety and Wellness*, covers CISD and CISM in detail.

Extrication and Special Rescue

Some MCIs or disasters require search and rescue or extrication of patients (**FIGURE 41-6**). An **extrication supervisor** or **rescue supervisor** may need to be appointed. These officers determine the type of equipment and resources needed for the situation. In some incidents, patients may need to be extricated or rescued before they can be triaged and treated. Because extrication and rescue are medically complex, the supervisors will usually function under the medical branch of the ICS. Extrication and rescue can be dangerous, so team safety is of utmost importance.

Morgue Supervisor

Some MCIs or disasters will result in many dead patients. The **morgue supervisor** works with area medical examiners, coroners, disaster mortuary assistance teams, and law enforcement agencies to coordinate removal of the bodies and even, possibly, body parts. The morgue supervisor should attempt to leave the dead patients in the location

FIGURE 41-6 Some disasters will involve search and rescue or extrication.

© Edward Keating/POOL/AP Photos.

found, if possible, until a removal and storage plan can be determined. The location of patients may help in the identification of the dead patients in mass-fatality situations, or there may be crime scene considerations. If it is determined that a morgue area is needed, then the morgue supervisor should ensure that the morgue area is out of view of the living patients and other responders because the psychological impact could worsen the situation. In addition, the morgue area should be secured from the public to prevent theft of any personal effects of the dead patients.

Mass-Casualty Incidents

As discussed previously, an MCI refers to any call that could overwhelm available community resources, and require a mutual aid response (**FIGURE 41-7**). Disasters certainly qualify as MCIs, but many other causes of MCIs are far more common than disasters and are usually much smaller in scope. **FIGURE 41-8** is a diagram of a residential building fire confined to one apartment that may only produce one patient but that has the potential to generate dozens of patients from among the responders and residents. Loss of power to a hospital or nursing home with ventilator-dependent and nonambulatory patients

is considered an MCI, although no one is injured. By using the ICS and the NIMS and understanding the various roles and responsibilities of each position, the responders and/or IC can manage the incident in a smooth, organized manner.

All EMS systems have different protocols for when to declare an MCI and/or initiate the ICS; however, as the AEMT, ask yourself the following questions when considering whether the call is an MCI:

- *How many seriously injured or ill patients can I effectively treat and transport in the ambulance? One? Two?*

FIGURE 41-7 In large mass-casualty incidents, such as the terrorist attacks on September 11, 2001, mutual aid may be necessary from many additional jurisdictions.

© REUTERS/Alamy Stock Photo.

- *What happens when I have multiple patients to manage?*
- *How long will it take for additional help to arrive?*
- *What happens if the number of patients exceeds the number of available ambulances?*

Obviously, you and your team cannot treat and transport all injured patients at the same time. At an MCI, you will often experience an increased demand for equipment and personnel. For example, you may realize that you are the only ambulance crew currently at the scene with a wait of 15 or more minutes before the next ambulance arrives. Never leave the scene to transport patients if other sick or wounded patients are still present. This action would leave patients at the scene without medical care and can be considered abandonment. If multiple patients are present and not enough resources are available to handle them without abandoning patients, you should declare an MCI (at least for the present time), request additional resources, and initiate the ICS and triage procedures (described next) (**FIGURE 41-9**). Although this process may cause some delay in initiating treatment to all patients, it will not adversely affect the patient care. Always follow your local protocol.

Triage

As discussed previously, triage is the sorting of patients based on the severity of their injuries.

FIGURE 41-8 Diagram of a mass-casualty incident. The incident command system established at the scene of a building fire may look similar to this diagram.

© Jones & Bartlett Learning.

The goal of doing the greatest good for the greatest number means that the triage assessment is brief and the patient condition categories are basic. **Primary triage** is the initial triage done in the field, allowing you to quickly and accurately categorize the patient's condition and transport needs, whereas **secondary triage** (or re-triage) is done as patients are brought to the treatment area. During primary triage, patients are briefly assessed and

FIGURE 41-9 Mass-casualty incidents require additional ambulances and EMS providers from the immediate region.

© John Lamparski/NurPhoto/Getty Images.

then identified in some way, such as by attaching a triage tag or triage tape (discussed next). The main information needed on the tag is a unique number and a triage category. Rapid and accurate triage will help bring order to the chaos of the MCI scene and allow the most critical patients to be transported first. After the primary triage, the triage supervisor should communicate the following information to the medical branch director:

- The total number of patients
- The number of patients in each of the triage categories
- Recommendations for extrication and movement of patients to the treatment area
- Resources needed to complete triage and begin movement of patients

When the primary triage has been completed, secondary triage can occur, allowing you to reassess all remaining patients and to upgrade the triage category, if necessary. In smaller MCI events, this step may not be necessary if enough resources have arrived on the scene.

Triage Categories

The four common triage categories can be remembered using the mnemonic IDME, which stands for

YOU are the Provider

Part 3

Patient No. 1 is a middle-aged woman who states she was in the lobby speaking with the receptionist when the building collapsed. She is alert and oriented, reporting a 2-inch (5-cm) laceration to her head, which appears to be venous. She keeps asking where her baby is.

Patient No. 2 is a middle-aged woman who is unresponsive but breathing adequately. You see what appears to be an abdominal evisceration.

Patient No. 3 is an older man who is screaming in pain. You note an obviously deformed left femur.

Patient No. 4 is a young adult man who has a large bruise on his right arm where a piece of the building struck him. He is able to move the arm and reports normal sensation throughout.

Patient No. 5 is a young adult man who is lying motionless on the ground. He is unresponsive and not breathing; you are unsure whether he has a pulse.

Patient No. 6 is a 7-month-old boy who is crying inconsolably. You see bruising in the abdominal area.

Patient No. 7 is a middle-aged woman who is lying motionless on the ground. You are able to hear snoring respirations at a rate of about 7 breaths/min.

5. Which triage category should be assigned to each of these patients?
6. Which patient should be transported first?

TABLE 41-1 Triage Priorities

Triage Category	Typical Injuries
Red tag: first priority (immediate) Patients who need immediate care and transport; treat these patients first, and transport as soon as possible.	• Airway and breathing compromise • Uncontrolled or severe bleeding • Severe medical emergencies • Signs of shock (hypoperfusion) • Severe burns • Open chest or abdominal injuries
Yellow tag: second priority (delayed) Patients whose treatment and transport can be temporarily delayed.	• Burns without airway compromise • Major or multiple bone or joint injuries • Back injuries with or without spinal cord damage
Green tag: third priority, minimal (walking wounded) Patients who require minimal or no treatment and transport can be delayed until last.	• Minor fractures • Minor soft-tissue injuries
Black tag: fourth priority (expectant) Patients who are already dead or have little chance for survival; treat salvageable patients before treating these patients.	• Obvious death • Obviously nonsurvivable injury, such as major open brain trauma • Respiratory arrest (if limited resources) • Cardiac arrest

© Jones & Bartlett Learning.

Immediate (red), Delayed (yellow), Minor or Minimal (green; hold), and Expectant (black; likely to die or dead) (**TABLE 41-1**). IDME is the order of priority for treatment and transport of the patients at an MCI.

Immediate (red-tag) patients are your first priority. They need immediate care and transport. They usually have problems with the airway, breathing, and circulation; head trauma; or signs and symptoms of shock.

Delayed (yellow-tag) patients are the second priority and need treatment and transport, but it can be delayed. Patients usually have multiple injuries to bones or joints, including back injuries with or without spinal cord injury.

Minimal (green-tag) patients are the third priority. Patients may require no field treatment or only minimal treatment. In some parts of the world, this is the hold category. These patients are the “walking wounded” at the scene. If they have any apparent injuries, then they are usually soft-tissue injuries such as contusions, abrasions, and lacerations.

The last priority is the expectant (black-tag) patients who are dead or whose injuries are so severe that they have, at best, a minimal chance of survival. This category may include patients who are

Words of Wisdom

An interesting development is the possible addition of a new, fifth triage category: the orange-tag category. This category represents an intermediate category between the critical (red-tag) and noncritical, nonambulatory (yellow-tag) patients. During a true MCI, there may be ambulatory patients who require prompt evaluation and treatment for symptoms that are the result of medical comorbidities and not the acute traumatic injuries associated with the initial event. Consider patients who are having nontraumatic chest pain or shortness of breath following the event. In the past, these patients may have been undertriaged as stable, requiring little or no treatment, simply because they were ambulatory. A patient placed in this intermediate category could be more appropriately prioritized for treatment and transport if the condition required a specific destination that was not a trauma center (eg, cardiac catheterization center or hyperbaric chamber). The New York City Simple Triage and Rapid Treatment (FDNY-START) system now incorporates the orange-tag category, and there may be ongoing developments as other systems adopt similar classifications.

in cardiac arrest or who have an open head injury, for example. If you have limited resources, then this category may also include patients in respiratory arrest. Patients in this category receive treatment and transport only after patients in the other three categories have received care.

Triage Tags

Whatever triage system is used, it is vital that a patient has a tag or some type of label. Tagging patients early assists in tracking them and can help keep an accurate record of their condition. Triage tags should be weatherproof and easily read (**FIGURE 41-10**). The patient tags or tape should be color-coded and should clearly show the category of the patients. The use of symbols, numbers, and colors to indicate the triage categories is important in case some responders are color-blind.

A

B

FIGURE 41-10 Triage tags. **A.** A START triage tag is ripped to the level of severity. **B.** A SMART triage tag folds to the level of severity.

A: © Nancy G Fire Photography/Nancy Greifenhagen/Alamy Stock Photo; B: Courtesy of Richard Pilbery.

The tags will become part of the patient's medical record. Most have a tear-off receipt with a number correlating with the number on the tag. When torn off by the transportation officer, the receipt will assist in tracking the patient. If the patient is unresponsive and cannot be identified at the scene, then the tag will be an identifier for tracking purposes. Some areas use digital photography to assist in identifying patients later. The photograph is catalogued with the patient's tag number, and the patient's location is tracked with this information. When family members are brought to crisis centers to help locate loved ones, the photographs may be of assistance. This technique has been used effectively in Europe and Israel with Polaroid or digital photographs. Another way of tracking and accounting for patients is to issue only 20 to 25 cards or tags at a time with a scorecard to mark how patients are triaged and their priority. When the responders return for more tags, the scorecard will provide a patient count to help command and the staff to develop a plan to respond and ensure that appropriate resources are either available or summoned. Whatever labeling system is used during triage, it is imperative for the transportation officer to be able to identify which patient was transported by which unit and to which destination, and the priority of the patient's condition.

START Triage

START triage is one of the easiest methods of triage. START stands for Simple Triage And Rapid Treatment. The staff members at Hoag Memorial Hospital, Newport Beach, CA, are responsible for developing this method of triage. It is easily mastered with practice and will give you the ability to rapidly categorize patients at an MCI. START triage uses a limited assessment of the patient's ability to walk, respiratory status, hemodynamic status (pulse), and neurologic status.

The first step of the START triage system is performed on arrival at the scene by calling out to patients at the incident site, "If you can hear my voice and are able to walk . . ." and then directing patients to an easily identifiable landmark. The injured people in this group are the walking wounded and are considered minimal (green) priority, or third-priority, patients.

The second step in the START process is directed toward nonwalking patients. Move to the first

nonambulatory patient and assess the respiratory status. If the patient is not breathing, then open the airway by using a simple manual maneuver. A patient who still does not begin to breathe is triaged as expectant (black). If the patient begins to breathe, then tag the patient as immediate (red), place in the recovery position, and move on to the next patient.

If the patient is breathing, then make a quick estimation of the respiratory rate. A patient who is breathing faster than 30 breaths/min or slower than 10 breaths/min is triaged as an immediate priority (red). If the patient is breathing at a rate of 10 to 29 breaths/min, then move to the next step in the START process.

The next step is to assess the hemodynamic status of the patient by checking for bilateral radial pulses. An absent radial pulse implies the patient is hypotensive; tag this patient as an immediate priority. If the radial pulse is present, then proceed to the next step.

The final assessment in START triage is to assess the patient's neurologic status, which simply

means to assess the patient's ability to follow simple commands, such as "Show me three fingers." This assessment establishes that the patient can understand and follow commands. A patient who is unresponsive or cannot follow simple commands is an immediate priority (red). A patient who complies with a simple command should be triaged in the delayed category (yellow).

JumpSTART Triage for Pediatric Patients

Lou Romig, MD, recognized that the START triage system does not take into account the physiologic and developmental differences of pediatric patients. She developed the **JumpSTART triage** system for pediatric patients. JumpSTART is intended for use in children younger than 8 years or who appear to weigh less than 100 pounds (45 kg). As in START, the JumpSTART system begins by identifying the walking wounded. Infants or children not developed enough to walk or follow commands (including children with special needs) should be taken to the treatment area as soon as possible for secondary triage. This action assists in getting children who cannot take care of their own basic needs into the hands of a health care provider. There are several differences within the respiratory status assessment compared with that in START. First, if you find that a pediatric patient is not breathing, then immediately check the pulse. If the patient has no pulse, then label the patient as expectant (black). If the patient is not breathing but has a pulse, then open the airway with a manual maneuver. If the patient does not begin to breathe, then give five rescue breaths and check respirations again. A child who does not begin to breathe should be labeled as expectant. The primary reason for this difference is that the most common cause of cardiac arrest in children is respiratory arrest.

The next step of the JumpSTART process is to assess the approximate rate of respirations. A patient who is breathing fewer than 15 breaths/min or more than 45 breaths/min is tagged as an immediate priority (red), and then you move on to the next patient. If the respirations are within the range of 15 to 45 breaths/min, then assess the patient further.

Just like in START, the next assessment in JumpSTART triage is also the hemodynamic status of the patient. You are simply checking for a distal pulse.

Special Populations

JumpSTART Triage

This system is intended for use in children younger than 8 years or who appear to weigh less than 100 pounds (45 kg). Assessment ends immediately when child is tagged.

1. Identify walking wounded = minimal (green).
2. Not breathing → check pulse.
 - No pulse = expectant (black).
 - Pulse present → open airway. If apneic, give five rescue breaths and reassess.
 - Still apneic = expectant (black).
3. Assess respirations.
 - <15 breaths/min or >45 breaths/min = immediate (red).
 - 15–45 breaths/min → continue assessment.
4. Assess distal pulse.
 - No pulse = immediate (red).
 - Pulse present → continue assessment.
5. Assess neurologic status (AVPU)
 - Unresponsive, response to pain by posturing or incomprehensible sounds, or unable to localize pain = immediate (red).
 - Alert or pain responsive by localizing or withdrawing from it = delayed (yellow).

This pulse does not need to be the brachial pulse; assess the pulse that you feel the most competent and comfortable checking. If you note an absence of a distal pulse, then label the child as an immediate priority (red) and move to the next patient. If the child has a distal pulse, then move on to the next assessment.

The final assessment is for neurologic status. Because of the developmental differences in children, their responses will vary. For JumpSTART, a modified AVPU scale (Awake and alert, responsive to Verbal stimuli, responsive to Pain, Unresponsive) is used. A child who is unresponsive, responds to pain by posturing or with incomprehensible sounds, or is unable to localize pain is tagged as an immediate priority (red). A child who responds to pain by localizing it or withdrawing from it or is alert is considered a delayed-priority patient (yellow).

Words of Wisdom

Another triage method is the Sort, Assess, Lifesaving interventions, and Treatment and/or Transport (SALT) triage system. This triage system begins with a global sorting of patients. This method identifies the patients who are able to understand verbal instructions and are therefore likely to have good systemic perfusion. Patients who can walk are asked to move to a designated area and are assigned as last priority.⁶ This is an attempt to decrease the number of patients leaving the scene and overwhelming local hospital resources before EMS can begin to move the highest priority patients. After those patients have been identified and moved, each remaining patient is assessed individually and life-saving interventions are performed.

The SALT triage method differs from other triage methods in its life-saving intervention steps, which include bleeding control, opening the airway, two rescue breaths for children, needle decompression for tension pneumothorax, and auto-injector antidotes. These interventions may be all that is needed to upgrade the patient's condition on the SALT triage scale. The final step is treatment and/or transport.

Special Considerations in Triage

A few special situations can occur in triage. Patients who are hysterical and disruptive to rescue efforts may need to be handled as an immediate priority (red) and transported out of the MCI or disaster

site, even if they are not seriously injured. Panic breeds panic, and this type of behavior could have a detrimental impact on other patients and on the responders.

A responder who becomes sick or injured during the rescue effort should be handled as an immediate priority (red) and be transported off the site as soon as possible to avoid negative impact to the morale of remaining responders.

Hazmat and weapons of mass destruction incidents force the hazmat team to identify patients as either contaminated or decontaminated before the regular triage process. Contamination by chemicals or biologic weapons in a treatment area, a hospital, or trauma center could obstruct all systems and organizations coping with the MCI or disaster. Bear in mind that some incidents may require multiple triage areas or teams because the patients are located far apart.

Destination Decisions

All patients triaged as immediate (red) or delayed (yellow) should preferably be transported by either ground ambulance or air ambulance, if available, to the most appropriate facility. In extremely large situations, a bus may transport the walking wounded. If a bus is used to transport minimal-priority patients, then it is strongly suggested that they be transported to a hospital or clinic distant from the MCI or disaster site to avoid overwhelming the local area hospital resources. If a bus is used, plan for at least one responder to ride on the bus and to have an ambulance follow the bus. If the condition of a minimal-priority patient worsens, then the patient could be moved to the ambulance and transported to a closer facility. The responder can stay with the minimal-priority patients until their arrival at the designated hospital. Any worsening of a patient's condition must be relayed to the receiving hospital as soon as possible in whatever manner the incident dictates. Refer to the Centers for Disease Control and Prevention 2011 decision scheme for field triage of injured patients presented in Chapter 26, *Trauma Overview*.

Immediate-priority patients should be transported two at a time until all are transported from the site. Then patients in the delayed category can be transported two or three at a time until all are at a hospital. Finally, the walking wounded are transported. Expectant patients who are still alive would

receive treatment and transport at this time. Dead patients are handled or transported according to the standing operating procedure for the area.

It is important to remember that during an MCI or disaster, local hospitals may have their resources overwhelmed. Early notification to receiving facilities will allow for the hospitals to increase staffing and move patients within their facility as required.

Words of Wisdom

Urban Search and Rescue teams (USARs) and Disaster Medical Assistance Teams (DMATs) may be mobilized in the event of a natural disaster or MCI. USARs typically provide rescue and initial medical stabilization to patients entrapped in confined spaces, such as from a structural collapse. DMATs provide medical care during an incident; they include providers such as physicians, paramedics, nurses, AEMTs, and EMTs who work at a federal level. DMATs arrive with sufficient supplies and equipment to provide care for at least 72 hours or until further aid arrives or the situation is resolved.

Typically, EMS agencies will know the surge capacity of a hospital, which will tell the agency how many patients of each category the hospital is able to safely handle and care for.

Disaster Management

A disaster is a widespread event that disrupts functions and resources of a community and threatens lives and property. Many disasters may not involve

Street Smarts

MCIs and disasters take a physical and emotional toll on emergency responders. Make certain that you are medically evaluated if you have been injured, come in contact with any hazardous substance, or inhale any dust, fumes, or smoke. Often the health effects of such exposures do not manifest for years and are difficult to link back to a particular event. Also be aware of the signs of stress in yourself and in your coworkers. Consider taking advantage of CISM or CISD opportunities after an incident.

YOU are the Provider

Part 4

As soon as you have finished triaging the patients that had been brought to your triage area, additional ambulance personnel arrive to assist you in treatment. You advise the IC of your triage findings and he advises you to assume the role of transportation officer, while the other crews are beginning their treatment. Knowing that your area hospitals have a trauma treatment plan for mass-casualty situations, you contact the three local hospitals to ascertain the number of critical patients they can accept. Each hospital states that they can accept two "reds" and one "yellow." You direct the first ambulance to transport one "red" and one "yellow" patient, the second ambulance to transport one "red" and one "green" patient, and the third ambulance to transport one "red" patient and the remaining "green" patients. The incident commander advises you that all the patients have been accounted for, and that you will not be receiving any additional patients. You acknowledge the information and proceed to the expectant patient.

Recording Time: 34 Minutes

Respirations	Absent
Pulse	Absent
Skin	Cool, pale, and clammy
Blood pressure	Unobtainable
Oxygen saturation (SpO₂)	Unobtainable
Pupils	Fixed and dilated

7. What factors should you consider when determining the appropriate transport destination?
8. Should you re-triage the expectant patient at this point?

FIGURE 41-11 Hurricane Katrina flooded nearly 80% of New Orleans, Louisiana.⁷

© DAVID J. PHILLIP/AFP/Getty Images.

personal injuries, such as droughts causing widespread crop damage. On the other hand, many disasters such as floods, fires, and hurricanes will result in widespread injuries. Unlike an MCI, which generally lasts no longer than a few hours, emergency responders will generally be on the scene of a disaster for days to weeks and sometimes months (as in the events in New Orleans, Louisiana following Hurricane Katrina in 2005) (**FIGURE 41-11**). Although you can “declare” an MCI as an AEMT, only an elected official can formally declare a disaster.

As an AEMT, your role in a disaster is to respond when requested and to report to the IC for assigned tasks. In a disaster with an overwhelming number of casualties, area hospitals may decide

that they cannot treat all patients at their facilities. In this case, they may mobilize medical and nursing teams with equipment and set up a **casualty collection area** at a facility near the scene, such as a warehouse. Once at the casualty collection area, the teams can perform triage, provide emergency medical care, and transport patients to the hospital on a priority basis.

If a casualty collection area is established, then it will be coordinated through the ICS in the same way as all other branches and areas of the operation. This step is usually done only in a major disaster such as an earthquake, when transportation to a hospital facility is either impossible or involves prolonged delays. It may take several hours to establish a casualty collection area.

YOU are the Provider SUMMARY

1. What is the NIMS?

Although most incidents are handled at the local level, the president of the United States directed the Secretary of Homeland Security to implement the National Incident Management System (NIMS) in March 2004. Major incidents require the involvement and coordination of multiple jurisdictions, functional agencies, and emergency response disciplines. The NIMS provides a consistent nationwide template to enable federal, state, and local governments, as well as private-sector and nongovernmental organizations, to work together effectively and efficiently. Two important underlying principles of the NIMS are flexibility and standardization. The organizational structure must be flexible enough to be rapidly adapted for use in any situation. The NIMS provides standardization in terminology, resource classification, personnel training, certification, and more. Another important feature of the NIMS is the concept of interoperability, which refers to the ability of agencies of different types or from different jurisdictions to communicate with each other.

2. Why is NIMS helpful to all emergency responders?

Even on calls involving a single patient and no need for additional support, the implementation of NIMS is helpful to identify the roles and responsibilities of each crew member, particularly if the incident escalates. The structure of NIMS enables a single authority to have overall responsibility to manage the incident.

3. What is the function of the staging supervisor?

The staging supervisor locates an area to stage equipment and responders, tracks unit arrivals, and releases vehicles and supplies when ordered by incident command. This person plans for efficient access to and exit from the disaster site and prevents traffic congestion among responding vehicles.

4. What is the function of the triage supervisor?

The primary duty of the triage supervisor is to ensure that all patients receive a preliminary assessment of their condition. AEMTs who perform triage will help move patients to the appropriate treatment sector. One of the most difficult aspects of being a triage supervisor is that you must not begin treatment until all patients are triaged, or you will compromise your triage efforts.

5. Which triage category should be assigned to each of these patients?

Patient No. 1 should be triaged as "green" or minimal because she is alert and oriented, with a venous laceration to her head, which does not appear to be life threatening.

Patient No. 2 should be triaged as "red" or immediate. This patient requires immediate treatment and transport because of her open abdominal injury and unresponsiveness.

Patient No. 3 should be triaged as "yellow" or delayed because of his obvious femur fracture. This patient requires treatment and transportation; however, it can be delayed for a short period until the immediate patients are treated.

Patient No. 4 should be triaged as "green" or minimal based on his minor injuries. This patient requires minimal or no treatment and transport can be delayed until last.

Patient No. 5 should be triaged as "black" or expectant. This patient is already dead or has little chance of survival.

Patient No. 6 should be triaged as "red" or immediate. On the basis of the JumpSTART triage system for pediatric patients, the patient is automatically placed into the immediate category because he is unable to walk or follow commands.

Patient No. 7 should be triaged as "red" or immediate. This patient requires immediate treatment and transport due to her unresponsiveness and airway and breathing difficulties.

6. Which patient should be transported first?

All "red" or immediate patients should be transported prior to any of the other patients. However, with limited resources, it may be appropriate to transport multiple patients in the same ambulance.

7. What factors should you consider when determining the appropriate transport destination?

During an MCI, remember that the resources of local hospitals may be overwhelmed as well. The staff must now prepare for a potentially large number of MCI patients in addition to the patients they are currently treating.

As soon as you declare an MCI, notify local hospitals, apprise them of the situation, and determine

YOU are the Provider SUMMARY *continued*

their surge capacity; this information will tell you how many patients of each category they are able to safely and effectively care for. It will also allow for the hospitals to increase their staffing and, if needed, move patients within their facility.

8. Should you re-triage the expectant patient at this point?

As soon as all patients have been triaged, and as resources allow, the patients should undergo a continual re-triage to determine if their category needs to be upgraded or if a patient has died.

Prep Kit

Ready for Review

- The National Incident Management System (NIMS) provides a consistent nationwide template to enable federal, state, and local governments, as well as private-sector and nongovernmental organizations, to work together effectively and efficiently. The NIMS is used to prepare for, prevent, respond to, and recover from domestic incidents, regardless of cause, size, or complexity, including acts of catastrophic terrorism and hazardous materials incidents.
- The four major NIMS components are Fundamentals and Concepts of NIMS, Resource Management, Command and

Coordination, and Communications and Information Management.

- The purpose of the incident command system is to enhance command, control, and communications abilities, ensure responder and public safety, achieve incident management goals, ensure the efficient use of resources, and treat patients.
- Preparedness involves the decisions made and basic planning done before an incident occurs.
- Your agency should have written disaster plans that you are regularly trained to carry out.
- At incidents that have a significant medical factor, the incident commander should appoint someone as the medical branch director. This person will supervise the primary roles of the medical group: triage, treatment, and transport of the injured.
- An MCI refers to any call that could overwhelm available resources, or which could require a mutual aid response.
- The goal of triage is to do the greatest good for the greatest number. This means that the triage assessment is brief and the patient condition categories are basic.
- The four basic triage categories can be recalled using the mnemonic IDME:
 - Immediate (red)
 - Delayed (yellow)
 - Minor or Minimal (green; hold)
 - Expectant (black; likely to die or dead)
- A disaster is a widespread event that disrupts functions and resources of a community and threatens lives and property.
- Many disasters, such as a drought that causes widespread crop damage, may not involve personal injuries.

Vital Vocabulary

casualty collection area An area set up by physicians, nurses, and other hospital staff near a major disaster or mass-casualty incident scene where patients can receive further triage and medical care.

closed incident An incident that is contained; all casualties are accounted for.

command In incident command, the position or positions that oversee the incident, establish the objectives and priorities, and develop a response plan; functions may include a public information officer, safety officer, and liaison officer.

command post The designated field command center where the incident commander and support staff are located.

demobilization The process of directing responders to return to their facilities when their work at an incident has finished.

disaster A widespread event that disrupts community resources and functions, in turn threatening public safety, citizens' lives, and property.

extrication supervisor In incident command, the person appointed to determine the type of equipment and resources needed for a situation involving extrication or special rescue; also called the rescue supervisor.

finance and administration In incident command, the section responsible for accounting of all expenditures.

freelancing When individual units or different organizations make independent and often inefficient decisions about the next appropriate action.

incident action plan An oral or written plan stating general objectives reflecting the overall strategy for managing an incident.

incident commander (IC) The overall leader of the incident command system to whom commanders or leaders of incident command system divisions report.

incident command system (ICS) An on-scene emergency management model specifically designed to provide for an integrated organizational structure that reflects the complexity and demands of an incident, including disasters and mass-casualty incidents. Also called the incident management system.

joint information center (JIC) An area designated by the incident commander, or a designee, in which public information officers from multiple agencies distribute information about the incident.

JumpSTART triage A sorting system for pediatric patients younger than 8 years or weighing less than 100 pounds (45 kg); the system is modified for infants because they cannot ambulate on their own.

liaison officer In incident command, the person who relays information and concerns among command, the general staff, and other agencies.

logistics In incident command, the section that procures and stockpiles equipment and supplies during an incident.

mass-casualty incidents (MCIs) Emergency situations that can place great demand on the equipment or personnel of the EMS system or have the potential to overwhelm available resources.

medical incident command In incident command, the position responsible for the triage, treatment, and transport of injured people; also known as the medical or emergency medical services branch of the incident command system.

morgue supervisor In incident command, the person who works with area medical examiners, coroners, and law enforcement agencies to coordinate the disposition of dead patients.

multiple-casualty incident Any situation with more than one patient, but which will not overwhelm available resources.

mutual aid response An agreement between neighboring emergency medical services systems to respond to mass-casualty incidents or disasters in each other's region when local resources are insufficient to handle the response.

National Incident Management System (NIMS) A Department of Homeland Security system designed to enable federal, state, and local governments, private-sector and nongovernmental organizations, and all other organizations who assume a role in emergency management to effectively and efficiently prepare for, prevent, respond to, and recover from domestic incidents, regardless of cause, size, or complexity, including acts of catastrophic terrorism and hazardous materials incidents.

open incident An incident that is not yet contained; there may be patients who have yet to be

located and the situation may be ongoing, producing more patients.

operations In incident command, the section that carries out the orders of the incident commander to help resolve the incident.

planning In incident command, the section that ultimately produces a plan to resolve any incident.

primary triage A type of patient sorting used to rapidly categorize patients; the focus is on speed in locating all patients and determining an initial priority as their conditions warrant.

public information officer (PIO) In incident command, the person who keeps the public informed and relays information to the press.

rehabilitation area The area that provides protection and treatment to all personnel working at an emergency; here, workers are medically monitored and receive any needed care as they enter and leave the scene.

rehabilitation supervisor In incident command, the person who establishes an area that provides protection for responders from the elements and the situation.

rescue supervisor In incident command, the person appointed to determine the type of equipment and resources needed for a situation involving extrication or special rescue; also called the extrication supervisor.

safety officer In incident command, the person who monitors the scene for conditions or operations that may present a hazard to responders and patients; the safety officer may stop an operation when responder safety is an issue.

secondary triage A type of patient sorting used in the treatment area that involves re-triage of patients.

single command system A command system in which one person is in charge, generally used with small incidents that involve only one responding agency or one jurisdiction.

span of control In incident command, the subordinate positions under the commander's direction to which the workload is distributed; the

ideal supervisor/worker ratio is one supervisor for three to seven workers.

staging supervisor In incident command, the person who locates an area to stage equipment and personnel and tracks unit arrival and deployment from the staging area.

START triage A patient sorting process that stands for Simple Triage And Rapid Treatment and uses a limited assessment of the patient's ability to walk, respiratory status, hemodynamic status, and neurologic status.

termination of command The end of the incident command structure when an incident draws to a close and the command structure is no longer necessary.

transportation area The area in a mass-casualty incident where ambulances and crews are organized to transport patients from the treatment area to receiving hospitals.

transportation supervisor In incident command, the person in charge of the transportation sector in a mass-casualty incident who assigns patients

from the treatment area to awaiting ambulances in the transportation area.

treatment area The location in a mass-casualty incident where patients are brought after being triaged and assigned a priority, where they are reassessed, treated, and monitored until transport to the hospital.

treatment supervisor In incident command, the person, usually a physician, who is in charge of and directs emergency medical services providers at the treatment area in a mass-casualty incident.

triage The process of sorting patients based on the severity of injury and medical need to establish treatment and transportation priorities.

triage supervisor In incident command, the person in charge of the incident command triage sector who directs the sorting of patients into triage categories in a mass-casualty incident.

unified command system A command system used in larger incidents in which there is a multi-agency response or multiple jurisdictions are involved.

Chapter 42

Terrorism Response and Disaster Management

NATIONAL EMS EDUCATION STANDARD COMPETENCIES

EMS Operations

Knowledge of operational roles and responsibilities to ensure patient, public, and personnel safety.

Mass-Casualty Incidents Due to Terrorism and Disaster

- Risks and responsibilities of operating on the scene of a natural or man-made disaster. (pp 1995–2020)

KNOWLEDGE OBJECTIVES

1. Describe international terrorism and domestic terrorism, and include some examples of incidents that have been caused by each one. (pp 1995–1996)
2. List examples of four different types of goals that commonly motivate terrorist groups to stage a terrorist attack. (p 1996)
3. Discuss the response plans that have been developed for active shooter events. (pp 1996–1998)
4. Describe weapons of mass destruction (WMDs), and include examples of the five categories of weapons that are considered WMDs. (pp 1998–1999)
5. Describe how the National Terrorism Advisory System relates to your daily activities as an advanced emergency medical technician (AEMT) and your ability to respond to and survive a terrorist attack. (pp 1999–2000)
6. Describe key observations you must make on each call to assist in the determination of whether an incident is related to terrorism. (pp 1999–2000)
7. Describe the critical response actions you must perform at a suspected terrorist event related to establishing and reassessing scene safety, personnel protection, notification procedures, and establishing command. (pp 2000–2002)
8. Discuss the history of chemical agents, the four main classifications, routes of exposure, effects on the patient, and patient care. (pp 2002–2008)
9. Discuss three categories of biologic agents, the routes of exposure, effects on the patient, and patient care. (pp 2008–2015)
10. Explain the role of emergency medical services in relation to syndromic surveillance and points of distribution during a biologic event. (pp 2015–2016)
11. Describe the history of nuclear/radiologic devices, sources of radiologic materials and dispersal devices, medical management of the patient, and protective measures to take during a nuclear/radiologic incident. (pp 2016–2019)
12. Describe the mechanisms of injury caused by incendiary and explosive devices, including the types and severity of blast injuries. (pp 2019–2020)

PHOTO: © David L. Ryan/The Boston Globe/Getty Images.

SKILLS OBJECTIVES

1. Demonstrate the steps you can take to establish and reassess scene safety based on a scenario of a terrorist event. (pp 2001–2002)
2. Demonstrate how to manage a patient who has been exposed to a chemical agent. (p 2002)
3. Demonstrate the use of the DuoDote Auto-Injector and/or the Antidote Treatment Nerve Agent Auto-Injector. (p 2006)

Introduction

The increase in terrorist activity in the United States makes it possible that you may be called on to respond to a terrorist event during your career. International terrorists and domestic groups have increased their targeting of civilian populations with acts of terror. Furthermore, groups and individuals with alleged ties to terrorist organizations may seek to carry out so-called copycat attacks. The question is not whether terrorists will strike again, but rather when and where they will strike. You must be mentally and physically prepared for the possibility of a terrorist event. It is imperative that all emergency medical services (EMS) providers attend specialized training sessions to learn as much as possible about not only caring for survivors of such attacks, but also how to remain safe while doing so.

The use of weapons of mass destruction (WMDs), also known as weapons of mass casualty (WMCs), further complicates the management of the terrorist incident and places you in greater danger. Although it is difficult to plan and anticipate a response to many terrorist events, several key principles apply to every response. This chapter describes types of terrorist events, personnel safety, and patient management and gives you tools to prepare to respond to these events. You will learn the signs, symptoms, and treatment of patients who have been exposed to nuclear, chemical, or biologic agents or an explosive attack. At the end of this chapter, you will be able to answer the following key questions:

- What are my initial actions?
- Whom should I notify, and what should I tell them?
- What type of additional resources do I require?
- How should I proceed to address the needs of the patients?

- How should I ensure the safety of myself, my partner, and the patients?
- What is the clinical presentation of a patient exposed to a WMD?
- How do I assess and treat a patient exposed to a WMD?
- How do I avoid becoming contaminated or cross-contaminated with a WMD agent?

What Is Terrorism?

No one is quite sure who the first terrorist was, but terrorist forces have been at work since early civilizations. Today, terrorists pose a threat to nations and cultures everywhere. International terrorism has brought a new fear into the lives of many American citizens. The US Department of Justice defines both **international terrorism** and **domestic terrorism** with these points:

- Involves violent acts or acts dangerous to human life that violate federal or state law
- Appears to be intended (i) to intimidate or coerce a civilian population; (ii) to influence the policy of a government by intimidation or coercion; or (iii) to affect the conduct of a government by mass destruction, assassination, or kidnapping

These two types of terrorism are primarily distinguished according to the individuals responsible for the act. International terrorism is committed by people associated with, or inspired by, a defined terrorist organization or nation. Domestic terrorism is committed by people hoping to further ideological causes relevant to national issues.¹

In the United States, domestic terrorists have struck multiple times in previous years. The mass shooting at an Orlando, Florida nightclub in 2016 and the Boston Marathon bombing in 2013 are

FIGURE 42-1 The bombings at the Boston Marathon in 2013 are a recent example of domestic terrorism.

© Bill Greene/The Boston Globe/Getty Images.

examples (**FIGURE 42-1**). Terrorist organizations are generally categorized based on their beliefs and goals. Only a small percentage of groups actually turn toward terrorism as a means to achieve their goals, such as the following:

1. **Violent religious/doomsday cults.** These groups are especially dangerous because they often seek apocalyptic violence or mass murder as a means to their ends. They see other religions or “nonbelievers” as worthy targets for death, and part of their apocalyptic doctrine is to eradicate or cleanse a region (or the entire earth) of those who do not practice their faith.
2. **Extremist political groups.** They may include violent separatist groups and those who seek political, religious, economic, and social freedom.
3. **Cyber terrorists.** They attack a population’s technological infrastructure as a means to draw attention to their cause (power grid, Internet, intranet, telecommunications).²
4. **Single-issue groups.** These include antiabortion groups, animal rights groups, anarchists, racists, and even ecoterrorists who threaten or use violence as a means to advance their cause.

Most terrorist attacks require the coordination of multiple terrorists or “actors” working together. For example, 19 hijackers worked together to commit the worst act of terrorism in American history on September 11, 2001 (**FIGURE 42-2**). At least four terrorists worked together to commit the London Subway bombings on July 7, 2005. However, in a few

FIGURE 42-2 The September 11, 2001, attacks on the World Trade Center in New York City accounted for the majority of the deaths caused by terrorists in 2001.

© Todd Hollis/AP Photo.

instances a single terrorist has struck with devastating results. Terrorists who acted alone carried out each of the Atlanta abortion clinic attacks in 1996 and the 1996 Summer Olympics attack.

Individual Terrorists and Active Shooter Events

An alarming new trend in domestic terrorism involves the concept of the **lone wolf terrorist attack**. This method has quickly become a frequent threat in the United States and has resulted in some of the most devastating attacks on US soil in recent years. In *Report: Lone Wolf Terrorism*, the National Security Critical Issue Task Force defines lone wolf terrorism as “the deliberate creation and exploitation of fear through violence or threat of violence committed by a single actor who pursues political change linked to a formulated ideology, whether his own or that of a larger organization, and who does not receive orders, direction, or material support from outside sources.”³

The motives of the lone wolf terrorist are not always clear. These attacks may target schools, music festivals, or even shopping centers and have been

FIGURE 42-3 The Pulse nightclub shooting in Orlando in 2016 was an example of a lone wolf terrorist attack.

Gerardo Mora/Stringer/Getty Images News/Getty Images.

difficult to predict. Examples of the lone wolf terrorist attack include the 2015 Emanuel Church shooting in Charleston, South Carolina; the Pulse nightclub shooting of 2016 in Orlando, Florida (**FIGURE 42-3**); and the 2017 Las Vegas, Nevada, shooting at the Route 91 Harvest music festival. The combined death toll from just those three events is more than 110 people, with the total number of injured people close to 1,000.

Many of these lone wolf terrorist attacks involve firearms instead of explosives; thus, these events are further classified as an **active shooter event**. The alarming increase in the frequency of these attacks has intensified discussion of who should be allowed to own guns and what types of guns should be available to civilians. Further, it has prompted the medical community to better prepare the public and first responders to treat casualties of these events. In 2013, the American College of Surgeons formed a committee to recommend best practices for improving survival during active shooter and intentional mass-casualty events. The committee's recommendations are known as the Hartford Consensus. The Hartford Consensus consists of four reports that have helped to shape national policy and provides a framework for educating both the public and first responders.

The Hartford Consensus recommends that a response plan designed for active shooter response should include the acronym THREAT: Threat suppression, Hemorrhage control, Rapid Extrication to safety, Assessment by medical providers, and Transport to definitive care. This plan encourages a continuum of care that begins with immediate

responders, those people who are present at the point and time that the attack occurs. The continuum of care proceeds with professional responders arriving at the scene and trauma professionals at the hospital.

The Hartford Consensus highlights the importance of early hemorrhage control. While education and training can help immediate responders truly make a difference and improve survival, there may not always be uninjured people available to help the injured. The Hartford Consensus recommends reevaluating the practice of staging away from the scene and having patients brought to the ambulance. Traditionally, it may take a significant amount of time for professional responders to reach injured patients after the threat has been neutralized and the scene has been declared safe for all responders to enter.

To provide more rapid care, many EMS organizations have revised the roles and responsibilities of personnel responding to an active shooter event, a concept referred to as Rescue Task Force. EMS crews may be equipped with ballistics vests and helmets so that they may be paired with law enforcement to assist with treatment and evacuation of injured people from an active scene. An active shooter scene follows the concept of cold, warm, and hot zones. The Rescue Task Force may enter the warm zone but does not enter the hot zone. A key component to the implementation of incorporating EMS crews with law enforcement teams who are moving forward into an active shooter scene is interagency training. For further discussion of response zones, see Chapter 40, *Vehicle Extrication, Special Rescue, and Hazardous Materials*.

Controversies

The ideal scenario would involve complete threat elimination before any additional responders enter the scene. Following a shooting at a large high school, the process of law enforcement searching the facility room by room and ensuring there are no threats to additional responders could take an hour or more. This delay would be fatal for many of the injured. There has not been a universally accepted solution to this debate, so make sure you discuss this topic with your agency and follow your local protocols and policies.

The recommendations from the Hartford Consensus also paved the way for the Stop the Bleed campaign. Launched in 2015 by the Department of Defense, this nationwide campaign promotes offering education on hemorrhage control to the public to help improve the willingness and effectiveness of immediate responders who are able to help save lives at the point of injury. As of September 2019, over one million people around the world have been trained to save a life through the Stop the Bleed campaign. See Chapter 27, *Bleeding*, for a detailed discussion of the Stop the Bleed campaign.

For the advanced emergency medical technician (AEMT) working in today's society, these new challenges all translate to the need to maintain a high degree of situational awareness, prepare yourself mentally and physically to respond to these types of events, and support educating those immediate responders to assist in saving lives.

Weapons of Mass Destruction

A **weapon of mass destruction (WMD)**, or **weapon of mass casualty (WMC)**, is any agent designed to bring about mass death, casualties, and/or massive damage to property and infrastructure (bridges, tunnels, airports, and seaports). To help remember the different kinds of WMDs, use the following two mnemonics: **B-NICE** (Biologic, Nuclear, Incendiary, Chemical, and Explosive weapons) and **CBRNE** (Chemical, Biologic, Radiologic, Nuclear, and Explosive weapons).

To date, terrorist groups have favored tactics that use explosive devices, such as truck bombs or pedestrian suicide bombers. Many previous terrorist attempts to use either chemical or biologic weapons to their full capacity have been unsuccessful.

Nonetheless, as an AEMT, you must understand the destructive potential of WMDs.

The motives and tactics of the new-age terrorist groups have begun to change. As with the doomsday cults, many terrorist groups participate in indiscriminate killing. This doctrine of total carnage makes the use of WMDs highly desirable. WMDs are relatively easy to obtain or create and are specifically geared toward killing large numbers of people. With the fall of the former Soviet Union, the technology and expertise to produce WMDs may be available to terrorist groups with sufficient funding. Moreover, the technical instructions for making WMDs can be found readily on the Internet; in fact, they have even been published on terrorist group websites.

Chemical Terrorism/Warfare

Chemical agents are manufactured substances that can have devastating effects on living organisms. They can be produced in liquid, gas, or solid form depending on the desired route of exposure and dissemination technique. Developed during World War I (WWI), these agents have been implicated in thousands of deaths since being introduced on the battlefield and have been used to terrorize civilian populations. These agents consist of the following types:

- Vesicants (blister agents)
- Respiratory agents (choking agents)
- Nerve agents
- Metabolic agents (cyanides)

Words of Wisdom

Chemical warfare may consist of agents in the form of a liquid, gas, or solid.

YOU are the Provider

Part 1

Your ambulance, along with the local fire department and law enforcement, is dispatched to a suspected terrorist incident. During a ceremony to honor war veterans, a moving truck sped through the crowd and struck the wall of a building. On impact, the front of the cab exploded. The front of the truck is crumpled and smoke is coming from the engine. Several patients are visible from your unit.

1. Given the situation, what are some unique concerns about this incident?
2. Is it safe for you to enter the scene? What should be done first?

Biologic Terrorism/Warfare

Biologic agents are organisms that cause disease. They are generally found in nature; for terrorist use, however, they are cultivated, synthesized, and mutated in a laboratory. The **weaponization** of biologic agents is performed to artificially maximize the target population's exposure to the germ, thereby exposing the greatest number of people and achieving the desired result.

The primary types of biologic agents that you may come in contact with during a biologic event include the following:

- Viruses
- Bacteria
- Toxins

Radiologic/Nuclear Terrorism

Only two incidents involving the use of a nuclear device are publicly known. During World War II (WWII), the cities of Hiroshima and Nagasaki in Japan were devastated when they were targeted with nuclear bombs. The awesome destructive power demonstrated by the attack ended WWII and has since served as a deterrent to nuclear war.

Some nations hold close ties with terrorist groups (known as **state-sponsored terrorism**) and have obtained some degree of nuclear capability.

It is also possible for a terrorist to secure radioactive materials or waste to perpetrate an act of terror. Compared with a nuclear weapon, these materials are far easier for a determined terrorist to acquire and require less expertise to use. The difficulties in developing a nuclear weapon are well documented. Radioactive materials, however, can cause widespread panic and civil disturbances. This topic will be covered later in this chapter.

Words of Wisdom

When you respond to a terrorist event, the basic foundations of patient care remain the same; however, the treatment can and will vary. Terrorist events can produce a single casualty, hundreds of casualties, or even thousands of casualties. In all cases, remember situational awareness. What you may do in one situation may not be appropriate for another situation. During large-scale terrorist events, it is important to perform triage and base your patient care on available resources.

Recognizing a Terrorist Event (Indicators)

Most acts of terror are **covert**, which means that the public safety community generally has no prior knowledge of the time, location, or nature of the attack. This element of surprise makes responding to an event more complex. You must constantly be aware of your surroundings and understand the possible risks for terrorism associated with certain locations, at certain times. It is therefore important that you know the current threat level issued by the federal government through the Department of Homeland Security (DHS).

In April 2011, the color-coded Homeland Security Advisory System was replaced by the National Terrorism Advisory System (NTAS). Alerts from the NTAS contain a summary of the threat and the actions that first responders, government agencies, and the public can take to maintain safety. On the basis of threat information, take appropriate actions and precautions while continuing to perform daily duties and respond to calls. The DHS has not issued specific recommendations for EMS personnel to follow in response to the alert system. Follow your local protocols, policies, and procedures.

It is your responsibility to make sure you are aware of information sent out by the NTAS at the start of your workday. Daily newspapers, television news programs, and multiple websites (including the DHS website) all give up-to-date information. Many EMS organizations are starting to display the NTAS on boards where it can be seen by staff when they arrive for a shift.

An understanding and awareness of the current threat level is only the beginning of responding safely to calls. When you are on duty, you must be able to make appropriate decisions regarding the potential for a terrorist event. In determining the potential for a terrorist attack, make the following observations on every call:

- **Type of location.** Is the location a monument, infrastructure, government building, or a specific type of location such as a temple? Is a large gathering of people present? Is a special event taking place?
- **Type of call.** Has an explosion or suspicious device been reported nearby? Does the call come into dispatch as someone having unexplained

coughing and difficulty breathing? Are there reports of people fleeing the scene?

- **Number of patients.** Are multiple patients reporting similar signs and symptoms? (This is probably the single most important clue that a terrorist attack or an incident involving a WMD has occurred.)
- **Patients' statements.** This is probably the second-best indication of a terrorist or WMD event. If the patients fleeing the scene are giving statements such as, "Everyone is passing out," "There was a loud explosion," or "There are a lot of people shaking on the ground," then something is occurring that you do not want to rush into, whether or not it is a terrorist event.
- **Preincident indicators.** Has a recent increase in violent political activism occurred? Are you aware of any credible threats made against the location, gathering, or occasion?

Response Actions

Once you suspect that a terrorist event has occurred or a WMD has been used, you must take action to ensure you will be safe and be in the proper position to help the community.

Scene Safety

Ensure the scene is safe. Remember to stage your vehicle a safe distance (usually 1 to 2 blocks) from the incident, and wait for law enforcement personnel to advise you that the scene has been made secure. If you have any doubt that it may be safe, then do not enter. When dealing with a WMD scene, it is safe to assume that you will not be able to enter where the event has occurred—nor do you want to. The best location for staging is upwind and uphill from the incident. Wait for assistance from those who are trained in assessing and managing WMD scenes. Expect that a perimeter will be created, usually by law enforcement personnel, in an effort to isolate the scene, prevent further contamination of evidence, and protect responders and the public from further danger. Also remember the following rules:

- Failure to park your vehicle at a safe location can place you and your partner in danger (**FIGURE 42-4**). It is important to always make an escape plan beforehand, in case the scene becomes unsafe.

FIGURE 42-4 Park your vehicle at a safe location.

© Dennis MacDonald/Alamy Stock Photo.

- If your vehicle is blocked in by other emergency vehicles or damaged by a secondary device or event (discussed later in this chapter), then you will be unable to provide patients with transportation or escape yourself.

Responder Safety (Personnel Protection)

The best form of protection from a WMD agent is to prevent yourself from coming in contact with the agent. The greatest threats facing you in a WMD attack are contamination and **cross-contamination**. Contamination with an agent occurs when you have direct contact with the WMD or are exposed to it. Cross-contamination occurs when you come in contact with a contaminated person who has not yet been decontaminated.

Words of Wisdom

One of the easiest ways to distinguish between a nonterrorist and a terrorist mass-casualty event is whether the intentional use of a WMD affects multiple people. These patients will generally exhibit the same signs and symptoms. It is highly unlikely for more than one person to experience a seizure at any given time. It is not uncommon to find multiple patients who report difficulty breathing at the scene of a fire. However, the same report in the subway at rush hour, when no smell of smoke has been reported, is certainly cause for suspicion. In these cases, use good judgment and resist the urge to rush in and help, especially when the situation involves multiple patients and an unknown cause.

Notification Procedures

If you suspect a terrorist or WMD event has taken place, then notify the dispatcher, provided that communications function properly. Vital information needs to be communicated effectively if you are to receive the appropriate assistance. Inform dispatch of the nature of the event, any additional resources that may be required, the estimated number of patients, and the upwind or optimal route of approach. See Chapter 4, *Communications and Documentation*, for information on effective communication.

It is extremely important to establish a staging area, where other units will converge. Be mindful of access and exit routes when you direct units to respond to a location. For example, it is unwise to have units respond to the front entrance of a hotel or apartment building where an explosion has occurred. See information on vehicle positioning in Chapter 39, *Transport Operations*.

Last, only trained responders in the proper personal protective equipment (PPE) are equipped to handle the WMD incident. These specialized units, traditionally hazardous materials (hazmat) teams, must be requested as early as possible because of the time required to assemble and dispatch the team and equipment. Many jurisdictions share hazmat teams, and the team may have to travel a long distance to reach the location of the event. It is always

better to be safe than sorry; call the team early, and the outcome of the call will be more favorable.

Finally, keep in mind that more than one type of device or agent may be present (discussed next).

Establishing Command

The first provider to arrive on the scene must begin to sort out the chaos and define their responsibilities under the incident command system (ICS). As the first person on scene, you may need to establish command until additional personnel arrive. Depending on the circumstances and stage of the operation, you and other AEMTs may function as medical branch directors, triage supervisors, treatment supervisors, transportation supervisors, logistic officers, or command and general staff. If the initial ICS is already in place, then immediately seek out the medical staging officer to receive your assignment. Chapter 41, *Incident Management*, discusses how to work within the ICS and the National Incident Management System.

Reassessing Scene Safety

Terrorists have been known to plant additional explosives that are set to explode after the initial bomb. This type of **secondary device** is intended primarily to injure responders and to secure media coverage because the media generally arrive on scene just after the initial response. Secondary devices may include various types of electronic equipment, such as a mobile phone that is designed to detonate when a call is answered. Do not rely on others to secure your safety. It is your responsibility to constantly assess and reassess the scene for safety. It is easy to overlook a suspicious package lying on the floor while you are treating casualties. Stay alert. Something as subtle as a change in the

Words of Wisdom

On September 11, 2001, communications in New York City were severely affected by the collapse of the World Trade Center. The primary communications repeater was situated on top of one of the towers. In addition, excess radio traffic made transmitting and receiving messages extremely difficult. Not only were radio communications affected, but also most mobile phones and most radio and television stations were disabled. The lesson learned from this event is to have multiple backups to ensure your ability to communicate with your dispatcher. In the event of a terrorist or WMD event, refrain from using the radio unless you have something important to transmit. If you do transmit, then gather your thoughts and speak as calmly as possible, avoiding unnecessary chatter. Remember that others may be unable to call for help while you are transmitting.

Street Smarts

If you are called on to treat a suspected criminal or suspected terrorist, then it is important that this patient receive the same emergency medical care as your other patients. Although it may be emotionally difficult for you to treat the patient, remember that you are not the judge or jury. It is up to the legal system to prove someone guilty in a court of law.

wind direction during a gas attack or an increase in the number of contaminated patients can place you in danger. Never become so involved with the tasks you are performing that you do not look around and make sure that the scene remains safe.

Chemical Agents

Modern-day chemical weapons were first developed during WWI and WWII. During the Cold War, many of these agents were perfected and stockpiled. Although the United States has long renounced the use of chemical weapons, many nations still develop and stockpile them. These agents are deadly and pose a threat if they are acquired by terrorists.

Chemical weapons have several classifications. The properties or characteristics of an agent can be described as liquid, gas, or solid material. **Persistence** and **volatility** are terms used to describe how long the agent will stay on a surface before it evaporates. Persistent or nonvolatile agents can remain on a surface for long periods, usually longer than 24 hours. Nonpersistent or volatile agents evaporate relatively fast when left on a surface in the optimal temperature range. An agent that is described as highly persistent can remain in the environment for weeks to months, whereas an agent that is highly volatile will turn from liquid to gas (evaporate) within minutes to seconds.

Route of exposure is how the chemical agent most effectively enters the body. Chemical agents can have either a vapor or contact hazard. Agents with a **vapor hazard** enter the body through the respiratory tract in the form of vapors. Agents with a **contact hazard** (or skin hazard) give off very little vapor or no vapors and enter the body through the skin.

Vesicants (Blister Agents)

The primary route of exposure of blister agents, or **vesicants**, is the skin (contact); however, if vesicants are left on the skin or clothing long enough, they produce vapors that can enter the respiratory tract. Vesicants cause burn-like blisters to form on the patient's skin and in the respiratory tract. The vesicant agents consist of sulfur mustard (H), lewisite (L), and phosgene oxime (CX) (the symbols H, L, and CX are military designations for these chemicals). The vesicants usually cause the most damage to damp or moist areas of the body, such as the armpits,

groin, and respiratory tract. Signs of vesicant exposure on the skin include the following:

- Skin irritation, burning, and reddening
- Immediate, intense skin pain (with L and CX)
- Formation of large blisters
- Gray discoloration of skin (a sign of permanent damage seen with L and CX)
- Swollen and closed or irritated eyes
- Permanent eye injury (including blindness)

If vapors were inhaled, then the patient may experience the following signs and symptoms:

- Hoarseness and stridor
- Severe cough
- Hemoptysis (coughing up blood)
- Severe dyspnea

Sulfur mustard (H) (commonly known as mustard gas) is a brown-yellow, oily substance that is generally considered very persistent. When released, H has the distinct smell of garlic or mustard and is quickly absorbed into the skin and/or mucous membranes. As the agent is absorbed into the skin, it begins an irreversible process of damage to the cells. Absorption through the skin or mucous membranes usually occurs within seconds, and damage to the underlying cells takes place within 1 to 2 minutes.

Mustard gas is considered a **mutagen**, which means that it mutates, damages, and changes cellular DNA. Eventually, cellular death will occur. On the surface, the patient will generally not produce any signs or symptoms until 4 to 6 hours after exposure (depending on concentration and amount of exposure) (**FIGURE 42-5**).

FIGURE 42-5 Skin damage resulting from exposure to sulfur mustard (H).

Courtesy of Dr. Saeed Keshavarz/RCCI, Research Center of Chemical Injuries/IRAN.

The patient will experience a progressive red- dening of the affected area, which will gradually de- velop into large blisters. These blisters are similar in shape and appearance to those associated with thermal second-degree burns. The fluid within the blisters does not contain any of the agent; however, the skin covering the area is considered to be con- taminated until decontamination by trained per- sonnel has been performed.

Mustard gas also attacks vulnerable cells within the bone marrow and depletes the body's ability to reproduce white blood cells. As with other burns, the primary complication associated with vesicant blisters is secondary infection; the depletion of the white blood cells leaves the patient with a decreased resistance to infections. Although sulfur mustard is regarded as persistent, it releases enough vapors when dispersed to be inhaled. This release creates upper and lower airway compromise. The result is damage and swelling of the airways. The airway compromise makes the patient's condition far more serious.

Lewisite (L) and **phosgene oxime (CX)** produce blister wounds similar to those caused by mustard gas. These agents are highly volatile and have a rapid onset of symptoms, as opposed to the delayed onset seen with mustard gas. These agents produce immediate intense pain and discomfort when contact is made. The patient's skin may have a gray dis- coloration at the contaminated site. Although tissue damage also occurs with exposure to L and CX, they do not cause the secondary cellular injury that is as- sociated with mustard gas.

Vesicant Agent Treatment

No antidotes for H or CX exposure are available. British antilewisite is the antidote for agent L; how- ever, due to its side effects, it is given at the hospital and is not carried by civilian EMS personnel. En- sure the patient has been decontaminated before you initiate treatment. The patient may require prompt airway support if any agent has been in- haled, but this intervention should not occur until after decontamination. Gain intravenous (IV) ac- cess and initiate transport as soon as possible. Gen- erally, burn centers are best equipped to handle the wounds and subsequent infections produced by vesicants. Follow your local protocols when decid- ing the transport destination.

Respiratory Agents (Choking Agents)

The respiratory agents are gases that cause im- mediate harm to the people exposed to them. The primary route of exposure for these agents is through the respiratory tract, which makes them an inhalation or vapor hazard. Once inside the lungs, they damage the lung tissue and fluid leaks into the lungs. These agents produce respiratory- related symptoms such as dyspnea, tachypnea, and pulmonary edema because of the inability for air exchange.

Chlorine (Cl) was the first chemical agent ever used in warfare. It has a distinct odor of bleach and creates a green haze when released as a gas. Initially it produces upper airway irritation and a choking

YOU are the Provider

Part 2

When the emergency call was dispatched, you requested additional EMS units to respond to the scene. The firefighters and two deputies approach the cab of the truck to assess the potential for fire and to determine the status of the driver. The driver is slumped over the steering wheel and is wearing a vest with wires protruding from the pockets. The wires appear to be burned through and the man has obvious burns to his face and arms. The truck is stable and the firefighters determine that no threat of fire is apparent.

3. As an AEMT, what level of knowledge should you possess regarding terrorism and WMDs?
4. What is a secondary device or event?
5. Does the potential for a secondary device exist at this scene?

sensation. The patient may later experience the following signs and symptoms:

- Shortness of breath
- Chest tightness
- Hoarseness and stridor as a result of upper airway constriction
- Gasping and coughing

With serious exposures, patients may experience pulmonary edema, complete airway constriction, and death. The fumes from a mixture of household bleach and ammonia create an acid gas that produces similar effects to those of Cl. According to the American Association of Poison Control Centers, in 2018 household cleaning substances were the second most frequent source of exposure in children and the fourth most frequent in adults.⁴

Do not confuse **phosgene** with phosgene oxime (a vesicant discussed earlier in this chapter). Not only has phosgene been produced for chemical warfare, it is also a product of combustion. It might be produced in a fire involving other chemicals, such as at a textile factory, or as a result of metalwork or burning Freon (a liquid chemical used in refrigeration). Therefore, you may encounter a person who has been exposed to this gas during the course of a normal call or at the scene of a fire. Phosgene is a very potent agent that has a delayed onset of symptoms, usually hours. Unlike chlorine, when phosgene enters the body, it generally does not produce severe irritation that would possibly cause individuals to leave the area or hold their breath. In fact, the odor produced by the chemical is similar to that of freshly mowed grass or hay. As a result, a high quantity of the gas may enter the body unnoticed. Initially, a mild exposure may include the following signs and symptoms:

- Nausea
- Chest tightness
- Severe cough
- Dyspnea on exertion

The patient with a severe exposure may present with dyspnea at rest and excessive pulmonary edema. (The patient will actually expel large amounts of fluid from the pulmonary edema in the lungs.) The pulmonary edema may be so severe that the patient continually coughs up white or pink-tinged fluid. A severe exposure produces such large amounts of fluid in the lungs that the

patient may develop hypovolemia and subsequently hypotension.

Respiratory Agent Treatment

The best initial treatment for any patient who has been exposed to a respiratory agent is to remove the patient from the contaminated atmosphere. This step should be done by trained personnel in the proper PPE. Aggressively manage the airway, breathing, and circulation (ABCs), paying particular attention to oxygenation, ventilation, and suctioning if required. Do not allow the patient to be active because this will worsen the condition. No antidotes to counteract the respiratory agents are available. Your primary goals for prehospital emergency medical care are to manage the ABCs, gain IV access, allow the patient to rest in a position of comfort with the head elevated, and initiate prompt transport. If the patient's condition does not improve with basic airway support, then consider requesting an advanced life support intercept. Continuous positive airway pressure may benefit some of these patients, but others will require more advanced airway management.

Nerve Agents

The **nerve agents** are among the deadliest chemicals developed. They are classified as WMDs. Nerve agents are not readily available to the general public and are extremely toxic and rapidly fatal with any route of exposure. Designed to kill large numbers of people with small quantities, nerve agents can cause cardiac arrest within seconds to minutes of exposure. Nerve agents, discovered while in search of a superior pesticide, are a class of chemical called organophosphates, which are found in household bug sprays, agricultural pesticides, and some industrial chemicals, at far lower strengths than in nerve agents. Organophosphates block an essential enzyme in the nervous system, causing the body's organs to become overstimulated and burn out.

G agents came from the early nerve agents, the G-series, which were developed by German scientists (hence the G) in the period after WWI and during WWII. The three G-series agents are all designed with the same basic chemical structure with slight variations to produce different properties. The two variations of these agents are lethality and

volatility. The following G agents are listed from high volatility to low volatility:

- **Sarin (GB).** Highly volatile colorless and odorless liquid. Turns from liquid to gas within seconds to minutes at room temperature. Highly lethal, with an LD_{50} of about 1 drop, depending on the purity. The LD_{50} is the standard measurement that represents the amount that will kill 50% of people who are exposed to this level.⁵ GB is primarily a vapor hazard, with the respiratory tract as the main route of exposure. This agent is especially dangerous in enclosed environments such as office buildings, shopping malls, and subway cars. When this agent comes in contact with the skin, it is quickly absorbed and evaporates. When GB is on clothing, it has the effect of **off-gassing**, which means that the vapors are continuously released over time (like perfume). Off-gassing contaminates the patient and the patient's clothing.
- **Soman (GD).** Twice as persistent as GB and five times as lethal. It has a fruity odor as a result of the type of alcohol used in the agent and generally has no color. This agent is both a contact and an inhalation hazard that can enter the body through skin absorption and through the respiratory tract. A unique additive in GD causes it to bind to the cells that it attacks faster than any other agent. This irreversible binding is called **aging**, which makes it more difficult to treat patients who have been exposed to GD.
- **Tabun (GA).** Approximately one-half as lethal as GB and 36 times more persistent. Under the proper conditions it will remain present for several days. It also has a fruity smell and an appearance similar to GB. The components used to manufacture GA are easy to acquire, and the agent is easy to manufacture, which make it unique. GA is both a contact and an inhalation hazard that can enter the body through skin absorption and through the respiratory tract.
- **V agent (VX).** Clear, oily agent that has no odor and looks like baby oil. VX was developed by the British after WWII and has chemical properties similar to the G-series agents. The difference is that VX is more than 100 times more lethal than GB and is extremely persistent

FIGURE 42-6 VX is the most lethal nerve agent. The dot on the penny demonstrates the amount needed to achieve the lethal dose.

© Jones & Bartlett Learning. Photographed by Kimberly Potvin.

(**FIGURE 42-6**). In fact, VX is so persistent that given the proper conditions, it will remain relatively unchanged for weeks to months. These properties make VX primarily a contact hazard because it lets off very little vapor. It is easily absorbed into the skin, and the oily residue that remains on the skin's surface is extremely difficult to decontaminate.

Nerve agents all produce similar symptoms but have varying routes of exposure. Nerve agents differ slightly in lethal concentration or dose and also differ in volatility. Some agents are designed to quickly become a gas (nonpersistent or highly volatile), whereas others remain liquid for a time (persistent or nonvolatile). These agents have been used successfully in warfare. After the nerve agent enters the body through skin contact or through the respiratory system, the patient will begin to exhibit a pattern of predictable symptoms. Like all chemical agents, the severity of the patient's symptoms will depend on the route of exposure of the agent and the amount of exposure. The resulting symptoms are described using the military mnemonic SLUDGEM and the medical mnemonic DUMBELS (**TABLE 42-1**). The DUMBELS mnemonic is more useful to you as an AEMT because it lists the more dangerous symptoms associated with exposure to nerve agents.

Only a handful of medical conditions are associated with the bilateral, excessively constricted (pinpoint) pupils (**miosis**) seen with nerve agent exposure. (Miosis is seen quickly in a patient with vapor exposure, but miosis may occur later after an isolated skin exposure. In some cases, the patient may have sustained both vapor and skin exposure.) Conditions such as a stroke (cerebrovascular

TABLE 42-1 Symptoms of Exposure to Nerve Agents

Military Mnemonic: SLUDGEM	Medical Mnemonic: DUMBELS (all age groups)
Salivation, Sweating	Diarrhea
Lacrimation (excessive tearing of the eyes)	Urination
Urination	Miosis (pinpoint pupils), Muscle weakness
Defecation	Bradycardia, Bronchospasm, Bronchorrhea (discharge of mucus from the lungs)
Gastric upset and cramps	Emesis
Emesis	Lacrimation (excessive tearing of the eyes)
Muscle twitching/ Miosis (pinpoint pupils)	Seizures, Salivation, Sweating

© Jones & Bartlett Learning.

accident), direct light to both eyes, and a drug overdose all can cause bilateral constricted pupils. Therefore, assess the patient for all of the signs and symptoms associated with SLUDGEM/DUMBELS to determine whether the patient has been exposed to a nerve agent.

Miosis is the most common symptom of nerve agent exposure and can remain for days to weeks. This symptom, along with the others listed in Table 42-1, will help you recognize exposure to a nerve agent early. The seizures that are associated with nerve agent exposure are unlike those found in patients with a history of seizure. The seizure will continue until the patient dies or until treatment is given with a nerve agent antidote kit.

Nerve Agent Treatment

Fatalities from severe nerve agent exposure occur as a result of respiratory complications, which lead to respiratory arrest. After the patient has been decontaminated, be prepared to treat aggressively. You can greatly increase the patient's chances of survival simply by providing airway and ventilatory support. As with all emergencies, securing the

ABCs is the best and most important treatment that you can provide. Often in patients exposed to these agents, seizures will begin and will not stop. These patients will require administration of nerve agent antidote kits in addition to support of the ABCs.

Medical treatment for nerve agent exposure may include the **DuoDote Auto-Injector**. The DuoDote kit contains 2.1 mg of atropine and 600 mg of pralidoxime chloride (2-PAM) and is delivered as a single dose through one needle. Atropine is used to block the nerve agent from affecting the body. However, because the nerve agent may remain in the body for long periods, 2-PAM is used to eliminate the agent from the body. Many of the symptoms described in the DUMBELS mnemonic will be reversed with the use of atropine. These medications are delivered using the same technique as the EpiPen autoinjector; however, many doses may need to be administered to see these results. The military form of this combination injector is the **Antidote Treatment Nerve Agent Auto-Injector (ATNAA)**.

Words of Wisdom

On March 20, 1995, members of Aum Shinrikyo, a Japanese cult, released sarin (GB) in the Tokyo subway. The first arriving medical responders were met with chaos as hundreds and then thousands of people fled the subway system. Many were contaminated and showed signs and symptoms of nerve agent exposure. In the end, more than 5,000 people sought medical care for exposure to GB, and 12 people died. None of the EMS personnel wore protective clothing, and most became cross-contaminated. Remember, you can avoid becoming exposed. Do not become a patient!

In some regions, AEMTs may carry the DuoDote kit on the unit and will be called on to administer the antidotes to themselves or their patients. Remember that you need to properly dispose of activated antidote kits into a sharps container. If your service carries a nerve agent antidote, then refer to your local protocols for dose and use information.

TABLE 42-2 provides a brief comparison of nerve agents.

TABLE 42-2 Nerve Agents

Name	Military Designation	Odor	Special Features	Onset of Symptoms	Volatility	Route of Exposure
Tabun	GA	Fruity	Easy to manufacture	Immediate	Low	Skin contact and vapor hazard
Sarin	GB	None (if pure) or strong	Will off-gas while on patient's clothing	Immediate	High	Primarily respiratory vapor hazard; extremely lethal if skin contact is made
Soman	GD	Fruity	Ages rapidly, making it difficult to treat	Immediate	Moderate	Contact with skin; minimal vapor hazard
V agent	VX	None	Most lethal chemical agent; difficult to decontaminate	Immediate	Very low	Contact with skin; no vapor hazard (unless aerosolized)

© Jones & Bartlett Learning.

Metabolic Agents (Cyanides)

Hydrogen cyanide (AC) and cyanogen chloride (CK) are both agents that affect the body's ability to use oxygen. **Cyanide** is a colorless gas that has an odor similar to almonds. The effects of the cyanides begin on the cellular level and are rapidly seen at the organ and system levels. Besides the nerve agents, metabolic agents are the only chemical weapons known to kill within seconds to minutes. Unlike nerve agents, however, these deadly gases are commonly found in many industrial settings. Cyanides are produced in massive quantities throughout the United States every year for industrial uses such as gold and silver mining, photography, and plastics processing. They are often present in fires associated with textile and plastic factories. In fact, cyanide is naturally found in the pits of many fruits in very low doses. AC and CK share many of the same symptoms. In low doses, these chemicals are associated with dizziness, light-headedness, headache, and vomiting. Higher doses will produce symptoms that include the following:

- Shortness of breath and gasping respirations
- Respiratory distress or arrest
- Tachypnea
- Flushed skin
- Tachycardia

- Altered mental status
- Seizures
- Coma
- Apnea
- Cardiac arrest

The symptoms associated with the inhalation of a large amount of cyanide will all appear within several minutes. Death is likely unless the patient is treated promptly.

Safety

As previously mentioned, the basic chemical ingredient in nerve agents is organophosphate. This common chemical is used in lesser concentrations for insecticides. Although industrial chemicals do not possess sufficient lethality to be effective WMDs, they are easy to acquire, inexpensive, and would have similar effects to the nerve agents. Agricultural aircraft (ie, crop-duster planes) could be used to disseminate these chemicals. Be cautious when responding to calls where insecticide equipment is stored and used, such as a farm or supply store that sells these products. The symptoms and medical management of patients with organophosphate insecticide poisoning are identical to those of the nerve agents.

Cyanide Agent Treatment

Cyanide binds with the body's cells, preventing oxygen from being used. Several medications act as antidotes, but most services do not carry them. After trained personnel wearing the proper PPE have removed the patient from the source of exposure, all of the patient's clothes must be removed to prevent off-gassing in the ambulance, even if no liquid contamination has occurred. Trained and protected personnel must decontaminate any patients who may have been exposed to liquid contamination before you can initiate treatment. Then support the patient's ABCs and gain IV access. Mild effects of cyanide exposure will generally resolve by simply removing the patient from the source of contamination and administering supplemental oxygen. Severe exposure, however, will require aggressive oxygenation and perhaps ventilation with supplemental oxygen. Always use a bag-mask device or oxygen-powered ventilator device to ventilate a patient who has been exposed to a metabolic agent. The agent can easily be passed on from the patient to you through mouth-to-mouth or mouth-to-mask ventilations. If no antidote is available, then initiate transport immediately.

Words of Wisdom

Cyanide impairs the body's ability to offload oxygen molecules at the cellular level. This creates a true hypoxia at the cellular level (and anaerobic metabolism) despite the presence of oxygen circulating in the bloodstream. Patients exposed to cyanide may have a normal pulse oximetry reading while exhibiting signs of dyspnea. Provide supplemental oxygen as needed and monitor end-tidal carbon dioxide (ETCO₂) levels.

TABLE 42-3 summarizes the chemical agents. The odors of the particular chemicals are provided for informational purposes only. The sense of smell is a poor tool to use to determine whether a chemical agent is present. Many people are unable to smell the agents, and the odor could be derived from another source. This information is useful to you if you receive reports from people who claimed to smell bleach or garlic, for example. Never enter a potentially hazardous area using your sense of smell to determine whether a chemical agent is present.

Biologic Agents

Biologic agents pose many difficult issues when used as a WMD. Biologic agents can be almost completely undetectable. Also, most of the diseases caused by these agents will be similar to other minor illnesses commonly seen by EMS providers.

Biologic agents are grouped as viruses, bacteria, and neurotoxins and may be spread in various ways. **Dissemination** is the means by which a terrorist will spread the agent—for example, poisoning the water supply or aerosolizing the agent into the air or ventilation system of a building. A **disease vector** is an animal that spreads disease, once infected, to another animal. For example, bubonic plague can be spread by infected rats, smallpox by infected people, and the Zika virus or West Nile virus by infected mosquitoes. How easily the disease is able to spread from one human to another human is called communicability. Some diseases, such as those caused by human immunodeficiency virus (HIV), are difficult to spread by routine contact. Therefore, communicability is considered low. In other instances when communicability is high, such as with smallpox, the person is considered **contagious**. Typically, routine standard precautions are enough to prevent contamination from contagious biologic organisms.

Words of Wisdom

Always make sure your patients have been thoroughly decontaminated by trained personnel before you come in contact with them. Chemical agents are primarily a vapor hazard, and all of the patient's clothing must be removed prior to you providing treatment to prevent off-gassing to you. Finally, never perform mouth-to-mouth or mouth-to-mask ventilation on a patient with a chemical agent exposure. Many of the vapors may linger in the patient's airway, and cross-contamination may occur.

Incubation period describes the time between the person becoming exposed to the agent and the appearance of the first symptom or symptoms. It is important to understand that although your patient may not exhibit signs or symptoms, the person may be contagious.

TABLE 42-3 Chemical Agents

Name	Military Designations	Odor	Lethality	Onset of Symptoms	Volatility	Primary Route of Exposure
Nerve agents	Tabun (GA) Sarin (GB) Soman (GD) V agent (VX)	Fruity or none	Most lethal chemical agents; can kill within minutes; effects are reversible with antidotes	Immediate	Moderate (GA, GD) Very high (GB) Low (VX)	GA: both GB: vapor hazard GD: both VX: contact hazard
Vesicants	Mustard (H) Lewisite (L) Phosgene oxime (CX)	Garlic (H) Geranium (L)	Causes large blisters to form; may severely damage upper airway if vapors are inhaled; severe, intense pain and gray skin discoloration (L and CX)	Delayed (H) Immediate (L, CX)	Very low (H, L) Moderate (CX)	Primarily contact, with some vapor hazard
Respiratory agents	Chlorine (Cl) Phosgene (CG)	Bleach Cut grass (CG)	Causes irritation choking (Cl); severe pulmonary edema (CG)	Immediate (Cl) Delayed (CG)	Very high	Vapor hazard
Cyanide agents	Hydrogen cyanide (AC) Cyanogen chloride (CK)	Almonds (AC) Irritating (CK)	Highly lethal chemical gases; can kill within minutes; effects are reversible with antidotes	Immediate	Very high	Vapor hazard

© Jones & Bartlett Learning.

Be aware of when you should suspect the use of biologic agents. If the agent is in the form of a powder, such as in the October 2001 attacks involving letters laced with anthrax powder appearing in the US mail, the incident must be handled by hazmat specialists. Patients who come in direct contact with the biologic agent need to be decontaminated before you initiate treatment.

Viruses

Viruses are germs that require a living host to multiply and survive. A virus is a simple organism and

cannot thrive outside of a host (living body). Once in the body, the virus invades healthy cells and replicates itself to spread through the host. As the virus spreads, so does the disease that it carries. Viruses move from host to host by direct methods, such as through respiratory droplets or vectors. A *vector* is any agent that acts as a carrier or transporter.

Viral agents that may be released during a biologic terrorist event pose an extraordinary problem for health care providers, especially those in EMS. Although some viral agents do have vaccines, no treatment is available for a viral infection other than certain antiviral medications. Because of this

characteristic, the following viruses have the potential to be used as agents of terrorism.

Most recently, in 2020, the coronavirus disease (COVID-19) affected the world in an unprecedented way. The virus, possibly originating in bats, mutated and became easily communicable among humans, spreading rapidly to become a worldwide pandemic. Many countries, including the United States, instituted quarantine and stay-at-home orders and mandated the closure of all nonessential businesses in an attempt to prevent further spread of the virus. Health care workers were faced with protecting themselves from contracting COVID-19 while caring for critically ill patients. This pandemic is discussed further in Chapter 2, *Workforce Safety and Wellness*.

Smallpox

Smallpox is a highly contagious disease. Take all forms of standard precautions to prevent cross-contamination. You will greatly reduce this risk simply by wearing exam gloves, a high-efficiency particulate air respirator, and eye protection. According to the World Health Organization, the last natural case of smallpox in the world was seen in 1977.⁶ Before the rash and blisters show, the illness will start with a high fever and body aches and headaches. The patient's temperature is usually in the range of 101°F to 104°F (38.3°C to 40°C).

An easy, quick way to differentiate the smallpox rash from other skin disorders is to observe the size, shape, and location of the lesions. In smallpox, all the lesions are identical in development. In other skin disorders, the lesions will be in various stages of healing and development. Smallpox blisters

begin on the face and extremities and eventually move toward the chest and abdomen. The disease is in its most contagious phase when the blisters begin to form (**FIGURE 42-7**). Unprotected contact with these blisters will promote transmission of the disease (**TABLE 42-4**). A vaccine exists to prevent smallpox; however, it has been linked to medical complications and, in rare cases, death. It should be noted that smallpox is the only disease humans have eradicated, and this success occurred through vaccination programs. Should an outbreak occur, the US government has enough vaccine to vaccinate every person in the United States.

Viral Hemorrhagic Fevers

Viral hemorrhagic fevers (VHFs) consist of a group of diseases caused by viruses that include the

FIGURE 42-7 In smallpox, all the lesions are identical in development. In other skin disorders, the lesions will be in various stages of healing and development.

Courtesy of CDC.

TABLE 42-4 Characteristics of Smallpox

Dissemination	Aerosolized for warfare or use in a terrorist attack
Communicability	High from infected people or items (such as blankets used by infected patients); person-to-person transmission possible
Route of exposure	Inhalation of airborne droplets (cough) or direct skin contact with blisters
Signs and symptoms	Severe fever, malaise, body aches, headaches, small blisters on the skin, bleeding of the skin and mucous membranes; incubation period is 10 to 12 d; duration of the illness is approximately 4 wk
Medical management	Standard precautions; no specific treatment; provide supportive care (ABCs)

Abbreviation: ABCs, airway, breathing, and circulation

Ebola, Rift Valley, Marburg, and yellow fever viruses, among others. This group of viruses causes the blood in the body to seep out from the tissues and blood vessels (**FIGURE 42-8**). Initially, the patient will have flulike symptoms, progressing to more serious symptoms such as internal and external hemorrhaging. Outbreaks are not uncommon in Africa and South America. Outbreaks in the United States, however, are extremely rare. Take all standard precautions when treating people with these illnesses. Mortality rates vary depending on

FIGURE 42-8 Viral hemorrhagic fevers cause the blood vessels and tissues to seep blood, resulting in ecchymosis (bruising), hemoptysis (coughing up blood), and blood in the patient's stool. Notice the severe discoloration in this patient with Crimean-Congo hemorrhagic fever, indicating internal bleeding.

Courtesy of Professor Robert Swanepoel/National Institute for Communicable Disease, South Africa.

the strain of virus, the patient's age and health condition, and the availability of a modern health care system (**TABLE 42-5**).

TABLE 42-5 Characteristics of Viral Hemorrhagic Fevers

Dissemination	Direct contact with an infected person's body fluids; can also be aerosolized for use in a terrorist attack
Communicability	Moderate from person to person or contaminated items
Route of exposure	Direct contact with an infected person's body fluids
Signs and symptoms	Sudden onset of fever, weakness, muscle pain, headache, and sore throat; all followed by vomiting and, as the virus runs its course, internal and external bleeding
Medical management	Standard precautions; no specific treatment for viral hemorrhagic fever; provide supportive care (ABCs) and treatment for shock and hypotension, if present

Abbreviation: ABCs, airway, breathing, and circulation

YOU are the Provider

Part 3

You initiate triage of the patients who were injured by the truck. Four patients need treatment and transport. Additional units arrive on scene and take over the care of these patients. A firefighter approaches and tells you the man in the truck is unresponsive but appears to be breathing.

Recording Time: 1 Minute

Appearance	Poor
Level of consciousness	Unresponsive
Airway	Appears patent from a distance
Breathing	Appears slow from a distance
Circulation	Unknown, with obvious burns on the face and arms

6. How should you proceed with your assessment of this patient?
7. Does the information about the terrorist threat affect your assessment of this patient?

Bacteria

Unlike viruses, **bacteria** do not require a host to multiply and live. Bacteria are much more complex and larger than viruses and can grow up to 100 times larger than the largest virus. Bacteria contain all the cellular structures of a normal cell and are completely self-sufficient. Most bacterial infections can be treated with antibiotics.

Most bacterial infections will generally begin with flulike symptoms, which can make it difficult for health care providers to identify whether the cause is a biologic attack or a natural epidemic.

Safety

Because humans are acceptable hosts and vectors for many viruses and bacteria, it is important for you to take standard precautions at all times. If you fail to take standard precautions, then you may not only become a host for a virus, but you may spread it as well. Remember, a virus spreads from person to person to survive, and many infectious diseases present like common colds.

Anthrax (Pulmonary and Cutaneous)

Anthrax (*Bacillus anthracis*) is caused by a deadly bacterium that lies dormant in a spore (protective shell). When exposed to the optimal temperature and moisture, the germ is released from the spore. The routes of exposure for anthrax bacteria are inhalation, cutaneous, and gastrointestinal (from consuming food that contains spores) (**FIGURE 42-9**). The inhalational form, or pulmonary anthrax, is the deadliest and often presents as a severe cold. Pulmonary anthrax is associated with an 80% or higher death rate if untreated.⁷ Antibiotics can be used to treat anthrax successfully. A vaccine to prevent anthrax infections is available. **TABLE 42-6** lists characteristics of anthrax.

Plague (Bubonic and Pneumonic)

The 14th-century plague that ravaged Asia, the Middle East, and finally Europe (the Black Death) killed an estimated 33 to 42 million people, which represented more than half of the European population at that time. Later on, in the early 19th century, almost 20 million people in India and China

FIGURE 42-9 Cutaneous anthrax.

Courtesy of James H. Steele/CDC.

TABLE 42-6 Characteristics of Anthrax

Dissemination	Aerosolized
Communicability	Only in the cutaneous form (rare)
Route of exposure	Through inhalation of spore, skin contact with spore, or direct contact with skin wound (cutaneous), or through ingestion
Signs and symptoms	Flulike symptoms, fever, respiratory distress with tachycardia, shock, pulmonary edema, and respiratory failure after 3 to 5 d of flulike symptoms
Medical management	Pulmonary: standard precautions, oxygen, ventilatory support if in pulmonary edema or respiratory failure, and transport Cutaneous: standard precautions, apply dry sterile dressing to prevent accidental contact with wound and fluids

© Jones & Bartlett Learning.

died due to plague. The plague's natural vectors are infected rodents and fleas. When a person is bitten by an infected flea or comes in contact with an infected rodent (or the waste of the rodent), the person can contract bubonic plague.

Bubonic plague infects the **lymphatic system** (a passive circulatory system in the body that bathes the tissues in lymph and works with the immune system). When this occurs, the patient's **lymph nodes** (area of the lymphatic system where

A

B

FIGURE 42-10 A. Plague bubo at lymph node under arm. B. Plague bubo at lymph node on neck.

A: Courtesy of James H. Steele/CDC; B: Courtesy of CDC.

infection-fighting cells are housed) become infected and grow. The glands of the nodes will grow large (up to the size of a tennis ball) and round, forming **buboes** (**FIGURE 42-10**). If left untreated, then the infection may spread through the body, leading to sepsis and possibly death. Bubonic plague is not contagious and is not likely to be seen in a bioterrorist incident.

Pneumonic plague (also known as plague pneumonia) is a lung infection that results from inhalation of plague bacteria. This form of the disease is contagious and has a much higher death rate than the bubonic form (**TABLE 42-7**).

Neurotoxins

Neurotoxins are the deadliest substances known to humans. The strongest neurotoxin is 15,000 times more lethal than VX and 100,000 times more lethal than GB. These toxins are produced from plants, marine animals, molds, and bacteria. The route of

TABLE 42-7 Characteristics of Plague

Dissemination	Aerosolized
Communicability	Bubonic: low, only from contact with fluid in buboes Pneumonic: high, from person to person
Route of exposure	Ingestion, inhalation, or cutaneous
Signs and symptoms	Fever, headache, muscle pain and tenderness, pneumonia, shortness of breath, extreme lymph node pain and enlargement (bubonic)
Medical management	Standard precautions, provide supportive care (ABCs), oxygen if indicated, and transport

Abbreviation: ABCs, airway, breathing, and circulation

© Jones & Bartlett Learning.

exposure for these toxins is through ingestion, inhalation from aerosols, or injection. Unlike viruses and bacteria, neurotoxins are not contagious and have a faster onset of symptoms. Although these biologic toxins have immense destructive potential, they have not been used successfully as a WMD.

Botulinum Toxin

The most potent neurotoxin is **botulinum**, which is produced by bacteria. When introduced into the body, this neurotoxin affects the ability of the nervous system to function. Voluntary muscle control diminishes as the toxin spreads. Eventually the toxin causes muscle paralysis that begins at the head and face and travels downward throughout the body. The patient's accessory muscles and diaphragm will become paralyzed, and the patient will go into respiratory arrest (**TABLE 42-8**).

Ricin

Although not as deadly as botulinum, **ricin** is still five times more lethal than VX. This toxin is derived from mash that is left from the castor bean (**FIGURE 42-11**). When introduced into the body, ricin causes pulmonary edema and respiratory and circulatory failure leading to death (**TABLE 42-9**).

The clinical picture depends on the route of exposure. Ricin is stable and extremely toxic by many

TABLE 42-8 Characteristics of Botulinum Toxin	
Dissemination	Aerosolized, food supply sabotage, or injection
Communicability	None
Route of exposure	Ingestion, inhalation
Signs and symptoms	Dry mouth, intestinal obstruction, urinary retention, constipation, nausea and vomiting, abnormal pupil dilation, blurred vision, double vision, drooping eyelids, difficulty swallowing, difficulty speaking, and respiratory failure as the result of paralysis
Medical management	Provide supportive care (ABCs), oxygen, and transport; provide ventilatory support in case of paralysis of the respiratory muscles; vaccine is available

Abbreviation: ABCs, airway, breathing, and circulation

© Jones & Bartlett Learning.

TABLE 42-9 Characteristics of Ricin	
Dissemination	Released into indoor or outdoor air (aerosolized); food and water contamination
Communicability	None
Route of exposure	Inhalation, ingestion, injection
Signs and symptoms	Inhaled: cough, difficulty breathing, chest tightness, nausea, muscle aches, pulmonary edema, and hypoxia Ingested: nausea and vomiting, internal bleeding, and death Injection: no signs except swelling at the injection site and death
Medical management	Provide supportive care (ABCs); no treatment or vaccine available

Abbreviation: ABCs, airway, breathing, and circulation

© Jones & Bartlett Learning.

FIGURE 42-11 These seemingly harmless castor beans contain the key ingredient for ricin, one of the most potent toxins known to humans.

Courtesy of Brian Prechtel/USDA.

routes of exposure, including inhalation. It is likely that 1 to 3 mg of ricin can kill an adult, and the ingestion of one seed can most likely kill a child. Although all parts of the castor bean are poisonous, it is the seeds that are the most toxic. Castor bean ingestion causes a rapid onset of nausea, vomiting, abdominal cramps, and severe diarrhea, followed by vascular collapse. Death usually occurs on the third day in the absence of appropriate medical intervention.

Ricin is least toxic by the oral route. This is probably a result of poor absorption in the gastrointestinal tract, some digestion in the gut, and, possibly, some expulsion of the agent as caused by the rapid onset of vomiting. Ingestion causes local hemorrhage and necrosis of the liver, spleen, kidneys, and gastrointestinal tract. Signs and symptoms of ricin ingestion appear 4 to 8 hours after exposure, as follows:

- Fever
- Chills
- Headache
- Muscle aches
- Nausea
- Vomiting

- Diarrhea
- Severe abdominal cramping
- Dehydration
- Gastrointestinal bleeding
- Necrosis of the liver, spleen, kidneys, and gastrointestinal tract

Inhalation of ricin causes nonspecific weakness, cough, fever, hypothermia, and hypotension. Symptoms occur about 4 to 8 hours after inhalation, depending on the inhaled dose. The onset of profuse sweating some hours later signifies the termination of the symptoms. Signs and symptoms of ricin inhalation are as follows:

- Fever
- Chills
- Nausea
- Local irritation of eyes, nose, and throat
- Profuse sweating
- Headache
- Muscle aches
- Nonproductive cough
- Chest pain
- Dyspnea
- Pulmonary edema
- Severe lung inflammation

- Cyanosis
- Seizures
- Respiratory failure

Treatment is supportive and includes both respiratory support and cardiovascular support as needed. Early intubation and ventilation, combined with treatment of pulmonary edema, are appropriate. IV fluids and electrolyte replacement are useful for treating the dehydration caused by profound vomiting and diarrhea.

TABLE 42-10 summarizes the biologic agents.

Roles of the AEMT During a Biologic Event

Syndromic Surveillance

Syndromic surveillance is the monitoring, usually by local or state health departments, of patients presenting to emergency departments and alternative care facilities, the recording of EMS call volume, and the use of over-the-counter medications. Patients with signs and symptoms that resemble influenza are particularly important to monitor. Local and state health departments monitor for an unusual influx of patients with these symptoms in

TABLE 42-10 Biologic Agents

Disease	Transmission Person to Person	Incubation Period	Duration of Illness	Lethality (approximate case fatality rates)
Pulmonary anthrax	No	1 to 6 d	3 to 5 d (usually fatal if untreated)	High
Pneumonic plague	High	2 to 3 d	1 to 6 d (usually fatal)	High unless treated within 12 to 24 h
Smallpox	High	7 to 17 d (average, 12 d)	4 wk	High to moderate
Viral hemorrhagic fever	Moderate	4 to 21 d	Death within 7 to 16 d	High to moderate, depending on type of fever
Botulinum poisoning	No	1 to 5 d	Death within 24 to 72 h; lasts months if patient does not die	High without respiratory support
Ricin poisoning	No	18 to 24 h	Death within 10 to 12 d if ingested	High

hopes of discovering an outbreak early. The role of EMS in syndromic surveillance is valuable in the overall tracking of a biologic terrorist event or infectious disease outbreak. Quality assurance personnel and dispatch operations need to be aware of an unusual number of calls from patients with unexplainable symptoms coming from a particular region or community (known as symptom clusters).

Street Smarts

In a mass-casualty incident, it is important to frequently communicate with your patient. Remember, your patient is probably scared and does not know what is going on. By explaining to your patient any delays that are occurring, as well as the actions you are taking, you may alleviate the patient's fears. Also, provide your patient with protection (eg, building materials, backboards, or tarps) in an effort to protect the patient from further harm.

Points of Distribution (Strategic National Stockpile)

Points of distribution (PODs) are existing facilities that are established for the mass distribution of antibiotics, chemical antidotes, antitoxins, vaccinations, and other medications and supplies during an emergency. These supplies may be released in deliveries known as “push packs” by the US Centers for Disease Control and Prevention (CDC) Strategic National Stockpile. These push packages have a delivery time of 12 hours anywhere in the country. In some regions, local and state municipalities have started to stockpile their own supplies to reduce the time delay.

Emergency medical technicians, AEMTs, and paramedics may be called on to assist in the delivery of the medications to the public (depending on local emergency management planning). Your role may include triage, treatment of seriously ill patients, and patient transport to the hospital. Most plans for PODs include at least one ambulance on standby for the transport of seriously ill patients.

Radiologic/Nuclear Devices

What Is Radiation?

Ionizing radiation is energy that is emitted in the form of rays, or particles. This energy can be found in **radioactive material**, such as rocks and metals.

Radioactive material is any material that emits radiation. This material is unstable, and it attempts to stabilize itself by changing its structure in a natural process called **decay**. While the substance decays, it gives off radiation until it stabilizes. The process of radioactive decay can take anywhere from minutes to billions of years; meanwhile, the substance remains radioactive.

The energy that is emitted from a strong radiologic source is **alpha radiation**, **beta radiation**, **gamma (x-ray) radiation**, or **neutron radiation**. Alpha particles are the least harmful penetrating type of radiation and cannot move through most objects. In fact, a sheet of paper or the body's skin easily stops them. Beta particles are slightly more penetrating than alpha particles and require a layer of clothing to stop them. Gamma rays are far faster and stronger than alpha and beta radiation. These rays easily penetrate through the human body and require lead or several inches of concrete to prevent penetration. Neutron particles are among the most powerful forms of radiation. Neutrons easily penetrate through lead and require several feet of concrete to stop them (**FIGURE 42-12**).

Sources of Radiologic Material

Thousands of radioactive materials are found on the earth. These materials are generally used for purposes that benefit humankind, such as medicine, killing germs in food (irradiation), and construction work. After radiologic material has been used for its purpose, the remaining material is called radiologic waste. Radiologic waste remains radioactive but has no more usefulness. Radioactive materials can be found at the following locations:

- Hospitals and other health care facilities with radiology departments
- Colleges and universities
- Chemical and industrial sites
- Nuclear power plants

Not all radioactive material is tightly guarded. Radiologic waste is often not guarded at all, which makes the use of radioactive material appealing to terrorists.

Radiologic Dispersal Devices

A **radiologic dispersal device (RDD)** is any container that is designed to disperse radioactive material using explosive material. This process

FIGURE 42-12 The penetrating potential of radiation. **A.** Alpha. **B.** Beta. **C.** Gamma. **D.** Neutron.

© Jones & Bartlett Learning.

would generally require the use of a bomb, hence the nickname “**dirty bomb**.” A dirty bomb has the potential to injure people with not only the radioactive material, but also the explosive material used to deliver it. The mere thought of an RDD creates fear in a population, and so the ultimate goal of some terrorists—fear—is accomplished. In reality, however, the destructive capability of a dirty bomb is limited to the explosives that are attached to it. Therefore, if the explosive is sufficient to kill 10 people without radioactive material, then it will also kill 10 people with the radioactive material added. Long-term injuries and illness may be associated with the use of an RDD, yet not much more than the bomb by itself would create. In short, the dirty bomb is an ineffective WMD.

Nuclear Energy

Nuclear energy is artificially produced by altering (splitting) radioactive atoms. The result is an immense amount of energy that usually takes the form of heat. Nuclear material is used in medicine, weapons, naval vessels, and power plants. Nuclear material gives off all forms of radiation, including neutrons (the deadliest type). Like radioactive material, when nuclear material is no longer useful, it becomes waste that is still radioactive.

Nuclear Weapons

As mentioned previously, the destructive energy of a nuclear explosion is unlike any other weapon in the world. That is why nuclear weapons, such

as missiles or bombs, are kept only in secure facilities throughout the world. Some nations have ties to terrorists and have actively attempted to build nuclear weapons. Yet the ability of these nations to deliver a nuclear weapon is incomplete. The threat of complete mutual annihilation is an effective deterrent. Therefore, the likelihood of a nuclear attack is extremely remote.

However, because of the collapse of the former Soviet Union, the whereabouts of many small nuclear devices are unknown. These small, suitcase-sized nuclear weapons are called **Special Atomic Demolition Munitions (SADM)s**. The SADM, or “suitcase nuke,” was designed to destroy individual targets, such as important buildings, bridges, tunnels, and large ships. According to one report on the safety and security of Russia’s nuclear arsenal, an estimated 84 Russian SADMs are missing as of the late 1990s.⁸ No other information or updates on the whereabouts of these devices have been made public.

Symptomatology

Patients who have been exposed to a known or suspected source of excessive radiation may have radiation poisoning or radiation sickness. The effects of radiation exposure will vary depending on the amount of radiation that a person receives and

the route of exposure. Radiation can be introduced into the body by all routes of exposure as well as through the body (irradiation). The patient can inhale radioactive dust from nuclear fallout or from a dirty bomb or have radioactive liquid absorbed into the body through the skin. Once inside the body, the radiation source will irradiate the person from within rather than from an external source (such as radiograph equipment). Some common signs of radiation poisoning are listed in **TABLE 42-11**. Additional injuries will occur with a nuclear blast such as thermal and blast trauma, trauma from flying objects, and eye injuries.

TABLE 42-11 Common Signs of Radiation Poisoning	
Low exposure	Nausea, vomiting, diarrhea, dizziness, headache
Moderate exposure	First-degree burns, hair loss, compromised immune system (death of white blood cells), and cancer
Severe exposure	Second- and third-degree burns, cancer, and death

© Jones & Bartlett Learning.

YOU

are the Provider

Part 4

The bomb squad has finished its assessment of the vest the man is wearing and the vehicle itself and found no remaining threat in or around the vehicle. Firefighters extricate the patient from the truck and place him on a long backboard. A rapid trauma assessment shows slow and shallow respirations, second-degree burns to his face and arms, and a rigid abdomen. He is ventilated with a bag-mask device and 100% oxygen and packaged for transport.

Recording Time: 8 Minutes

Respirations	6 breaths/min
Pulse	122 beats/min, weak and thready
Skin	Pale and cool; burns to face and arms
Blood pressure	88/54 mm Hg
Oxygen saturation (Spo ₂)	89% on room air
Pupils	Pupils Equal, Round, and Reactive to Light and Accommodation (PERRLA)

8.

What potential injuries might you anticipate as a result of the explosion?

9.

Do you need to take any special decontamination measures after this call?

Medical Management

Being exposed to a radiation source does not make a patient contaminated or radioactive. However, when patients have a radioactive source on their bodies (such as debris from a dirty bomb), they are contaminated and must be initially cared for by a hazmat responder. After the patient is decontaminated and no threat to you exists, you may begin treatment with the ABCs and treat the patient for any burns or trauma. As always, wear appropriate PPE. Use plastic bags to secure any body fluids obtained from the patient. Place all body fluids in containers and properly dispose of them with other potentially radioactive waste.

Protective Measures

No suits or protective gear can completely shield you from radiation. The people who work in high-risk areas wear some protection like lead-lined suits; however, this equipment is not available to AEMTs. The best ways to protect yourself from the effects of radiation are to use time and distance and shield yourself using buildings and walls for protection. Do not enter a hazmat area unless you are trained as a hazmat responder and have proper training in the use of self-contained breathing apparatus.

- **Time.** Radiation has a cumulative effect on the body. The less time that you are exposed to the source, the less the effects will be. If you realize that the patient is near a radiation source, then leave the area immediately.
- **Distance.** Radiation is limited as to how far it can travel. Depending on the type of radiation, often moving only a few feet is enough to remove you from immediate danger. Alpha radiation cannot travel more than a few inches, but gamma rays can travel hundreds or thousands of feet. Take this into account when responding to a nuclear or radiologic incident, and make certain that responders are stationed far enough from the incident.
- **Shielding.** As discussed earlier, the path of all radiation can be stopped by a specific object. It will be impossible for you to recognize the type of radiation being emitted or even from which direction it is coming. Therefore, always assume that you are dealing with the strongest form of radiation and use concrete shielding

(such as buildings or walls) between yourself and the incident. The importance of shielding cannot be overemphasized.

Incendiary and Explosive Devices

Incendiary and explosive devices come in various shapes and sizes. Incendiary devices are weapons used to start fires. Terrorists use flamethrowers, chemicals, Molotov cocktails, or other explosive devices for this purpose. Although you are not required to recognize all of the possible types of explosive devices (including improvised explosive devices), it is important for you to be able to identify an object you believe is a potential device, notify the proper authorities, and safely evacuate the area. Always remember that the possibility of a secondary device exists when you respond to the scene of an incendiary or explosive device call.

Mechanisms of Injury

The type and severity of wounds sustained from incendiary and explosive devices primarily depend on the patient's distance from the epicenter of the explosion. Patients close to the epicenter of the explosion are likely to suffer from all wound-causing agents of the munitions. Patients who are farther away from the epicenter are likely to experience a combination of blast injuries from the explosion and penetrating trauma injuries from primary and secondary projectiles created by the explosion.

The five types of blast injuries are as follows:

- **Primary blast injury.** Caused solely by the direct effects of the pressure wave on the body. The injury from the primary blast is seen almost exclusively in the hollow organs of the body—the lungs, intestines, and inner ears. An injury to the lungs causes the greatest morbidity and mortality.
- **Secondary blast injury.** Penetrating or nonpenetrating injury that results from being struck by flying debris, such as ordnance projectiles or secondary missiles, that has been set in motion by the explosion. Objects are propelled by the force of the blast and strike the person, causing injury.
- **Tertiary blast injury.** Injury that results from whole-body displacement and subsequent

traumatic impact with environmental objects (eg, trees, buildings, and vehicles).

- **Quaternary blast injury.** Any other injury caused by a blast, including toxic inhalation of combustible gases (carbon monoxide, cyanide, etc); flash burns, crush injuries, respiratory injuries, and medical emergencies sustained while fleeing the scene (eg, a myocardial infarction); or mental health conditions (eg, posttraumatic stress disorder, even without the presence of any other injuries).
- **Quinary blast injury.** Injuries caused by exposure to toxic materials associated with radiation (dirty bombs), bacteria, and/or chemicals resulting in contamination of tissues, or by exposure to foreign bodies that have the potential to transmit disease. Signs and symptoms are related to the type of agent.⁹

For an illustration of blast injuries, see the Categories of Blast Injuries section in Chapter 26, *Trauma Overview*.

Words of Wisdom

A phenomenon known as “human remains shrapnel” is also a part of the quinary phase. This finding is often seen in suicide bombings in which a bone fragment from the assailant pierces the skin of a patient. Treatment of the patient is based on presentation: impaled object, open fracture, laceration, etc. However, penetration of the skin by allogeneic fragments (those coming from another individual) also carry the risk of transmission of bloodborne diseases such as HIV or hepatitis B. Always wear appropriate PPE and notify hospital staff of the potential for exposure.

The Physics of an Explosion

When a substance is detonated, a solid or liquid is chemically converted into large volumes of gas under high pressure with resultant explosive energy release. Propellants, such as gunpowder, are explosives designed to release energy relatively slowly compared with high-energy explosives, which are designed to detonate quickly. This detonation generates a pressure pulse in the shape of a spherical blast wave that expands in all directions from the point of explosion. Flying debris and high winds commonly cause conventional blunt and penetrating trauma.

Tissues at Risk

Hollow organs such as the middle ear, lung, and gastrointestinal tract are most susceptible to pressure

changes. The junction between tissues of different densities and exposed tissues such as the head and neck are prone to injury as well. The ear is the organ system most sensitive to blast injuries. The patient may report ringing or pain in the ears or some loss of hearing, and blood may be visible in the ear canal. Permanent hearing loss is possible.

Primary **pulmonary blast injuries** occur as contusions and hemorrhages in the lungs. According to the CDC, **blast lung** (a severe pulmonary contusion, bleeding, or swelling with damage to the blood vessels and alveoli or a combination of any or all) is the most common cause of death in people who survive the initial explosion. Blast lung is characterized by the clinical triad of apnea, bradycardia, and hypotension.¹⁰ When the explosion occurs in an open space, the patient's side that is toward the explosion is usually injured, but the injury can be bilateral when the patient is located in a confined space. The patient may report tightness or pain in the chest and may cough up blood and have tachypnea or other signs of respiratory distress. Subcutaneous emphysema (crackling under the skin) over the chest may be palpated, indicating the presence of air in the thorax. Pneumothorax is common and may require emergency decompression.

Solid organs are relatively protected from shock-wave injury but may be injured by secondary missiles or a hurled body. Hollow organs, however, may be injured by similar mechanisms as are lung tissue. Petechiae, or pinpoint hemorrhages that show up on the skin, to large hematomas are the most visible signs.

Neurologic injuries and head trauma are common causes of death from blast injuries. Subarachnoid (beneath the arachnoid layer covering the brain) and subdural (beneath the outermost covering of the brain) hematomas are often seen. Permanent or transient neurologic deficits may be secondary to concussion, intracerebral bleeding, or air embolism. Instant but transient unresponsiveness, with or without retrograde amnesia, may be initiated not only by head trauma, but also by cardiovascular conditions. Bradycardia and hypotension are common after an intense pressure wave from an explosion. This is a vagal nerve-mediated form of cardiogenic shock without compensatory vasoconstriction (for example, vasovagal syncope).

Extremity injuries, including traumatic amputations, are common and often accompanied by other significant injuries. Patients with traumatic amputation are likely to sustain fatal injuries secondary to the blast.

YOU are the Provider SUMMARY**1. Given the situation, what are some unique concerns about this incident?**

This incident presents a variety of concerns for you as an AEMT. Scene safety and situational awareness are paramount. You need to take special precautions with regard to vehicle positioning to protect yourself, patients, and bystanders from further injury. Because smoke is coming from the cab of the truck, be aware of the potential for fire and possible explosions. Also, because the truck is carrying an unknown load, the potential for a secondary event exists.

2. Is it safe for you to enter the scene? What should be done first?

Because of the potential for fire and explosion, the scene is not safe for you to enter at the present time. You should position the ambulance back far enough from the scene until the fire department and law enforcement have removed the threats. However, if other patients are located a safe distance away from the scene, then you can start triage and treatment of these patients.

3. As an AEMT, what level of knowledge should you possess regarding terrorism and WMDs?

You are not expected to be an expert in terrorism and WMDs. However, you are expected to be aware of the various types of threats (just like any other citizen) and recognize certain indicators of terrorism when responding to an incident. Always maintain a high index of suspicion and stay alert.

4. What is a secondary device or event?

A secondary device is an additional explosive that is set to detonate after the initial bomb. Such devices are intended primarily to injure responders and to secure media coverage because the media generally arrive on scene just after the initial response. Secondary devices may include various types of electronic equipment, such as a mobile phone that is designed to detonate when a call is answered.

5. Does the potential for a secondary device exist at this scene?

At scenes of terrorist activity, the potential for secondary devices always exists. This incident was an intentional attack on a group of people, and the driver of the truck was wearing an obvious explosive

device. Until qualified responders declare the scene safe, you should remain at a safe distance and proceed with emergency medical care of the other patients as needed.

6. How should you proceed with your assessment of this patient?

After the other patients have been turned over to the additional responding units, you are free to attend to the last patient—the truck driver. Do not approach the truck until scene safety is assured. Perform your assessment as you would with any other patient, with particular attention to scene safety.

7. Does the information about the terrorist threat affect your assessment of this patient?

Because no other assailants have been found, you can proceed with your assessment after the scene is deemed safe by qualified responders. The fact that this was a terrorist event does not change your assessment of this patient. Remain alert for any potential secondary devices and remember that if this patient becomes responsive, then he may be violent.

8. What potential injuries might you anticipate as a result of the explosion?

Injuries seen during the primary phase of a blast include those that affect gas-filled organs. Because the patient was wearing an explosive vest, he was close to the blast. Potential injuries include damage to the lungs, ruptured tympanic membranes, and other gas-filled organs. He also has burns to the face and arms.

9. Do you need to take any special decontamination measures after this call?

In this case, the patient and the vehicle were thoroughly evaluated before you assessed him and decontamination was deemed unnecessary, so you do not need to take any special decontamination measures beyond your regular measures after a call. If the patient had sustained possible contamination due to an agent he may have been transporting, then you would need to decontaminate anything that came in contact with the patient, including the ambulance, any equipment, and yourself. Decontamination must occur prior to putting the ambulance back into service and prior to delivering the patient to the hospital.

YOU are the Provider **SUMMARY** *continued***EMS Patient Care Report (PCR)**

Date: 10-6-21	Incident No.: 20108412	Nature of Call: MVC and multiple pedestrian injuries		Location: 107 Veterans Blvd	
Dispatched: 1204	En Route: 1205	At Scene: 1209	Transport: 1320	At Hospital: 1337	In Service: 1619

Patient Information

Age: Unknown	Allergies: Unknown
Sex: M	Medications: Unknown
Weight (in kg [lb]): 102 kg (224 lb)	Past Medical History: Unknown
	Chief Complaint: Altered mental status and burns to face and arms

Vital Signs

Time: 1308	BP: Not obtained	Pulse: Not obtained	Respirations: Slow	Spo₂: Not obtained
Time: 1315	BP: 88/54	Pulse: 122	Respirations: 6	Spo₂: 89% on room air

EMS Treatment (circle all that apply)

Oxygen @ ____ L/min via (circle one): NC NRM Bag-mask device		Assisted Ventilation	Airway Adjunct: Oral	CPR
Defibrillation	Bleeding Control	Bandaging	Splinting	Other:

Narrative

EMS dispatched to above location for report of MVC—truck vs pedestrians then struck brick building. Upon arrival found 4 pedestrians with obvious injuries and a moving truck with damage to front situated against brick wall of building. Smoke noted to be coming from truck engine. Attended pedestrian patients until turned over to additional units. Delayed care of driver of truck due to safety concerns. After scene was deemed safe by FD and law enforcement special unit, approached truck to find male patient sitting in driver's seat, apparently unresponsive with slow respirations. Patient was extricated by FD. Exposed and performed rapid trauma assessment—findings of second-degree burns to face and arms and rigid abdomen. 100% oxygen provided via bag-mask device with oral adjunct in place, burns covered with sterile sheet and patient packaged for transport. Transported emergency to trauma center. Upon arrival at ED report given to trauma team without incident. Law enforcement also standing by at ED.

End of report

Prep Kit**Ready for Review**

- As a result of the increase in terrorist activity, it is possible that you, the AEMT, could witness a terrorist event. You must be mentally and physically prepared for the possibility of a terrorist event.
- Types of groups that tend to use terrorism include violent religious groups/doomsday cults, extremist political groups, technology terrorists, and single-issue groups.
- Single-terrorist and active shooter events are becoming increasingly common. Both EMS providers and the civilian population are developing response plans to assist the victims of these attacks while maintaining personal safety.

- A weapon of mass destruction (WMD) is any agent designed to bring about mass death, casualties, and/or massive damage to property and infrastructure (bridges, tunnels, airports, and seaports).
- Use the following two mnemonics to help you remember the different kinds of WMDs: B-NICE (Biologic, Nuclear, Incendiary, Chemical, and Explosive weapons) and CBRNE (Chemical, Biologic, Radiologic, Nuclear, and Explosive weapons).
- Indicators that may give you clues as to whether the emergency is the result of a terrorist attack include the type of location, type of call, number of patients, patients' statements, and preincident indicators.
- If you suspect that a terrorist or a WMD event has occurred, then ensure the scene is safe. If you have any doubt that it may not be safe, then do not enter. Wait for assistance.
- Terrorists may set secondary devices that are designed to explode after the initial bomb, thus injuring responders and securing media coverage. Constantly assess and reassess the scene for safety.
- Chemical agents are manufactured substances that can have devastating effects on living organisms. They include vesicants (blister agents), respiratory agents, nerve agents, and metabolic agents.
- The route of exposure is how the agent most effectively enters the body.
- Biologic agents are organisms that cause disease. They include viruses such as smallpox and those that cause viral hemorrhagic fevers, bacteria such as those that cause anthrax and plague, and neurotoxins such as botulinum toxin and ricin.
- Radiologic or nuclear weapons can create a massive amount of destruction.
- Explosive and incendiary devices come in various shapes and sizes. It is important to be able to identify an object you believe is a potential device and notify the proper authorities, while safely evacuating the area.

Vital Vocabulary

active shooter event An act of terror in which firearms are used in an ongoing assault of multiple people.

aging The process by which the temporary bond between the organophosphate and acetylcholinesterase undergoes hydrolysis, resulting in a permanent covalent bond.

alpha radiation A type of energy that is emitted from a strong radiologic source; it is the least harmful penetrating type of radiation and cannot travel more than a few inches or through most objects.

anthrax A disease caused by deadly bacteria (*Bacillus anthracis*) that lie dormant in a spore (protective shell); the germ is released from the spore when exposed to the optimal temperature and moisture. The routes of entry are inhalation, cutaneous, and gastrointestinal (from consuming food that contains spores).

Antidote Treatment Nerve Agent Auto-Injector (ATNAA) The military form of a nerve agent antidote kit containing atropine and pralidoxime chloride; delivered as a single dose through one needle.

bacteria Single-cell microorganisms that rapidly reproduce by binary fission; some can form spores (encysted variants) when environmental conditions are harsh.

beta radiation A type of energy that is emitted from a strong radiologic source; is slightly more penetrating than alpha radiation and requires a layer of clothing to stop it.

blast lung A severe pulmonary contusion, bleeding, or swelling with damage to the blood vessels and alveoli, or a combination of any or all of these.

B-NICE A mnemonic to recall the types of weapons of mass destruction: Biologic, Nuclear, Incendiary, Chemical, and Explosive; see also CBRNE.

botulinum Produced by bacteria; when introduced into the body, this most potent of neurotoxins affects the ability of the nervous system to function and causes botulism.

buboes Enlarged lymph nodes (up to the size of a tennis ball) that are characteristic in people infected with the bubonic plague.

bubonic plague Bacterial infection that affects the lymphatic system; it is transmitted by infected rodents and fleas and characterized by acute malaise, fever, and the formation of tender, enlarged, inflamed lymph nodes that appear as lesions. Also called the Black Death.

CBRNE A mnemonic used to recall the types of weapons of mass destruction: Chemical, Biologic, Radiologic, Nuclear, and Explosive; see also *B-NICE*.

chlorine (Cl) The first chemical agent ever used in warfare; it has a distinct odor of bleach and creates a green haze when released as a gas. Initially it produces upper airway irritation and a choking sensation.

contact hazard The danger posed by an agent whose primary route of exposure is through the skin; also called a skin hazard.

contagious An infectious disease that can be transmitted to another; communicable.

covert An act in which the public safety community generally has no prior knowledge of the time, location, or nature of the attack.

cross-contamination Occurs when a person is contaminated by an agent as a result of coming in contact with another contaminated person.

cyanide A colorless gas that affects the body's ability to use oxygen; it has an odor similar to almonds. The effects begin on the cellular level and are rapidly seen at the organ and system levels.

decay A natural process in which a material that is unstable attempts to stabilize itself by changing its structure.

dirty bomb Any container that is designed to disperse radioactive material; see also *radiologic dispersal device*.

disease vector An animal that spreads a disease, once infected, to another animal.

dissemination The means by which a terrorist will spread an agent, such as by poisoning the water supply or aerosolizing the agent into the air or ventilation system of a building.

domestic terrorism Terrorism that is carried out by people hoping to further ideological causes relevant to the nation in which they are acting.

DuoDote Auto-Injector A nerve agent antidote kit containing atropine and pralidoxime chloride; delivered as a single dose through one needle.

G agents Early nerve agents that were developed by German scientists in the period after World War I and into World War II: sarin, soman, and tabun.

gamma (x-ray) radiation A type of energy that is emitted from a strong radiologic source that is far faster and has more energy than alpha and beta radiation. These rays easily penetrate through the human body and require lead or several inches of concrete to prevent penetration.

incubation period The time between when a person is exposed to an agent to when symptoms first appear.

international terrorism Terrorism that is carried out by people associated with, or inspired by, a defined terrorist organization or nation; also known as cross-border terrorism.

ionizing radiation Energy that is emitted in the form of rays or particles.

LD₅₀ The standard measure of the dose amount of an agent or substance that will kill 50% of a population who are exposed to this level.

lewisite (L) A vesicant that has a rapid onset of symptoms and produces immediate, intense pain and discomfort on contact; British antilewisite is the antidote.

lone wolf terrorist attack An act of terror carried out by a single person to further an ideological goal.

lymph nodes Round or bean-shaped structures interspersed along the course of the lymph vessels, where infection fighting cells are housed, and which filter the lymph and serve as a source of lymphocytes.

lymphatic system A passive circulatory system in the body that transports a plasmlike liquid called lymph, a thin fluid that bathes the tissues of the body.

miosis Excessively constricted (pinpoint) pupil; often bilateral after exposure to nerve agents.

mutagen A substance that mutates, damages, and changes the structures of the body's cells.

nerve agents A class of chemical called organophosphates; they function by blocking an essential enzyme in the nervous system, which causes

the body's organs to become overstimulated and burn out.

neurotoxins Biologic agents that are the most deadly substances known to humans; they include botulinum toxin and ricin.

neutron radiation The type of energy that is emitted from a strong radiologic source, involving particles that are among the most powerful forms of radiation; the particles easily penetrate through lead and require several feet of concrete to stop them.

off-gassing The release of an agent after exposure, such as from a person's clothes that have been exposed to the agent.

persistence Describes how long a chemical agent will stay on a surface before it evaporates.

phosgene A very potent respiratory agent that is a product of combustion; it has a delayed onset of symptoms, usually hours.

phosgene oxime (CX) A vesicant that has a rapid onset of symptoms and produces immediate, intense pain and discomfort on contact.

pneumonic plague A lung infection, also known as plague pneumonia, that is the result of inhalation of plague-causing bacteria.

points of distribution (PODs) Existing facilities used as mass distribution sites for antibiotics, chemical antidotes, antitoxins, vaccinations, and other medications and supplies during an emergency.

primary blast injury An injury caused by an explosive pressure wave on the hollow organs of the body.

pulmonary blast injuries Pulmonary trauma resulting from short-range exposure to the detonation of high-energy explosives.

quaternary blast injury A blast injury that falls into one of the following categories: burns, crush injuries, toxic inhalation, medical emergencies, or mental health disorders.

quinary blast injury A blast injury caused by exposure to toxic materials associated with radiation, bacteria, and/or chemicals resulting in contamination of tissues, or by foreign bodies that have the potential to transmit disease.

radioactive material Any material that emits radiation.

radiologic dispersal device (RDD) Any container that is designed to disperse radioactive material; see also *dirty bomb*.

ricin A neurotoxin derived from mash that is left from the castor bean; causes pulmonary edema and respiratory and circulatory failure leading to death.

route of exposure The manner by which a toxic substance enters the body.

sarin (GB) A nerve agent that is one of the G agents; a highly volatile, colorless, and odorless liquid that turns from liquid to gas within seconds to minutes at room temperature.

secondary blast injury A penetrating or nonpenetrating injury caused by ordnance projectiles or secondary missiles.

secondary device An explosive used by terrorists that is set to explode after the initial bomb; it is intended primarily to injure responders and to secure media coverage.

smallpox A highly contagious disease; it is most contagious when blisters begin to form.

soman (GD) A nerve agent that is one of the G agents; twice as persistent as sarin and five times as lethal; it has a fruity odor, as a result of the type of alcohol used in the agent; and is a contact and an inhalation hazard that can enter the body through skin absorption and through the respiratory tract.

Special Atomic Demolition Munitions (SADM) Small, suitcase-sized nuclear weapons that were designed to destroy individual targets, such as important buildings, bridges, tunnels, and large ships.

state-sponsored terrorism Terrorism that is funded and/or supported by nations that hold close ties with terrorist groups.

sulfur mustard (H) A vesicant also known as mustard gas; it is a brown-yellow, oily substance that is generally considered very persistent; has the distinct smell of garlic or mustard; and, when released, is quickly absorbed into the skin and/or mucous membranes and begins an irreversible process of damaging the cells.

syndromic surveillance The monitoring, usually by local or state health departments, of patients presenting to emergency departments

and alternative care facilities, the recording of EMS call volume, and the use of over-the-counter medications.

tabun (GA) A nerve agent that is one of the G agents; is 36 times more persistent than sarin and approximately one-half as lethal; has a fruity smell; and is unique because the components used to manufacture the agent are easy to acquire and the agent is easy to manufacture.

tertiary blast injury An injury from whole-body displacement and subsequent traumatic impact with environmental objects.

V agent (VX) One of the G agents; it is a clear, oily agent that has no odor and looks like baby oil; more than 100 times more lethal than sarin and is extremely persistent.

vapor hazard The danger posed by an agent that enters the body through the respiratory tract.

vesicants Blister agents; the primary route of exposure for this agent is through the skin.

viral hemorrhagic fevers (VHFs) A group of diseases caused by viruses that include the Ebola, Rift Valley, and yellow fever viruses, among

others. This group of viruses causes the blood in the body to seep out from the tissues and blood vessels.

viruses Germs that require a living host to multiply and survive.

volatility Describes how long a chemical agent will stay on a surface before it evaporates.

weapon of mass casualty (WMC) Any agent designed to bring about mass death, casualties, and/or massive damage to property and infrastructure (bridges, tunnels, airports, and seaports); also known as a weapon of mass destruction.

weapon of mass destruction (WMD) Any agent designed to bring about mass death, casualties, and/or massive damage to property and infrastructure (bridges, tunnels, airports, and seaports); also known as a weapon of mass casualty.

weaponization The creation of a weapon from a biologic agent generally found in nature and that causes disease; the agent is cultivated, synthesized, and/or mutated to maximize the target population's exposure to the germ.

Glossary

abandonment Unilateral termination of emergency medical care by the AEMT without the patient's consent and without making provisions for transferring care to another medical professional with the skills and training necessary to meet the patient's needs.

abdomen The body cavity that contains the major organs of digestion and excretion. It is located below the diaphragm and above the pelvis.

abdominal aortic aneurysm (AAA) A condition in which the walls of the aorta in the abdomen weaken and blood leaks into the layers of the vessel, causing it to bulge.

abdominal-thrust maneuver The preferred method to dislodge a severe airway obstruction in adults and children; also called the Heimlich maneuver.

abduction Movement of a limb *away* from the midline of the body.

abortion Delivery of the fetus and placenta before 20 weeks' gestation; a spontaneous abortion is called a miscarriage.

ABO system The antigen classification given to blood.

abrasion The loss or damage of the superficial layer of skin as a result of a body part rubbing or scraping across a rough or hard surface.

abruptio placentae Premature separation of the placenta from the wall of the uterus.

absence seizures Seizures that may be characterized by a brief lapse of attention in which the patient may stare and does not respond; formerly known as a petit mal seizure.

absorption In pharmacology, the process by which medications travel through body tissues until they reach the bloodstream; in allergic reactions, when foreign material is deposited on and moves into the skin.

acceleration The speeding up of an object.

access Gaining entry to an enclosed area and reaching a patient.

access port A sealed hub on an administration set designed for sterile access to the intravenous fluid.

accessory muscles The secondary muscles of respiration that include the neck muscles (sternocleidomastoids), the chest's pectoralis major muscles, and the abdominal muscles.

acetabulum The depression on the lateral pelvis where its three component bones join, in which the femoral head fits snugly.

acid A substance that increases the concentration of hydrogen ions in a solution.

acidosis A pathologic condition that results from the accumulation of acids in the body; an increase in extracellular H⁺ ions; a blood pH of less than 7.35.

acquired immunity The immunity that occurs when the body is exposed to a foreign substance antigen, or disease, and produces antibodies to the invader.

acquired immunodeficiency syndrome (AIDS) The end-stage disease process caused by the human immunodeficiency virus (HIV). A person with AIDS is extremely vulnerable to numerous infections.

acrocyanosis A decrease in the amount of oxygen delivered to the extremities. The hands and feet turn blue because of narrowing (constriction) of small arterioles (tiny arteries) toward the end of the arms and legs; can occur at any age; may be benign in infants younger than 2 months.

acromioclavicular (AC) separation One or more torn ligaments in the acromioclavicular joint, resulting in a separated shoulder.

acromion process The tip of the shoulder and the site of attachment for the clavicle and various shoulder muscles.

action The expected therapeutic effect of a medication on the body.

activation Mediators of inflammation trigger the appearance of molecules known as selectins and integrins on the surfaces of endothelial cells and polymorphonuclear neutrophils, respectively.

active compression-decompression CPR A technique that involves compressing the chest and then actively pulling it back up to its neutral position or beyond (decompression); may increase the amount of blood that returns to the heart and, thus, the amount of blood ejected from the heart during the compression phase.

active shooter A gunman who has begun to fire on people and is still at large.

active shooter event An act of terror in which firearms are used in an ongoing assault of multiple people.

active transport A method used to move compounds across a cell membrane to create or maintain an imbalance of charges.

activities of daily living (ADLs) The basic activities a person usually accomplishes during a normal day, such as eating, dressing, and washing.

acute abdomen A condition of sudden onset of pain within the abdomen, usually indicating peritonitis; demands immediate medical or surgical treatment.

acute chest syndrome A vaso-occlusive crisis that can be associated with pneumonia; common signs and symptoms include chest pain, fever, and cough.

acute coronary syndrome (ACS) A term used to describe a group of symptoms caused by myocardial ischemia; includes angina and myocardial infarction.

acute kidney injury (AKI) A sudden decrease in filtration through the glomeruli of the kidneys.

acute myocardial infarction (AMI) Heart attack; death of heart muscle following obstruction of blood flow to it. Acute in this context means new or happening right now.

acute stress reactions Reactions to stress that occur during a stressful situation.

adduction Movement of a limb *toward* the midline of the body.

adenosine triphosphate (ATP) The nucleotide involved in energy metabolism; used to store energy.

adhesion The attachment of polymorphonuclear neutrophils to endothelial cells, mediated by selectins and integrins.

administration set Tubing that connects to the intravenous bag access port and the catheter to deliver the intravenous fluid.

adolescent A young person age 12 to 18 years.

adrenal cortex The outer layer of the adrenal gland; it produces hormones that are important in regulating the water and salt balance of the body.

adrenal glands Endocrine glands located on top of the kidneys that release adrenaline when stimulated by the sympathetic nervous system.

adrenaline Hormone produced by the adrenal glands that mediates the “fight-or-flight” response of the sympathetic nervous system; also called epinephrine.

adrenergic Pertaining to nerves that release the neurotransmitter norepinephrine or noradrenaline; also pertains to the receptors acted on by norepinephrine.

adrenocorticotrophic hormone (ACTH) Hormone that targets the adrenal cortex to secrete cortisol (a glucocorticoid).

adult protective services (APS) An organization that investigates cases involving abuse and neglect and provides case management services in some cases.

advance directive Written documentation that specifies medical treatment for a competent patient should the patient become unable to make decisions; also see *health care directive*.

advanced emergency medical technician (AEMT) An individual trained in specific aspects of advanced life support, such as intravenous therapy and administration of certain emergency medications.

- advanced life support (ALS)** Advanced life-saving procedures used to treat medical conditions, such as cardiac monitoring, administration of intravenous fluids and medications, and the use of advanced airway adjuncts. EMTs and AEMTs may be trained in some of these areas.
- adventitious breath sounds** Abnormal breath sounds such as wheezes, rhonchi, and crackles.
- adventitious sounds** Abnormal breath sounds that include crackles, rhonchi, wheezes, stridor, and pleural friction rubs.
- aerobic metabolism** The metabolism that takes place in the presence of oxygen.
- aerosol-generating procedures (AGPs)** Treatments that increase the risk for transmission of infections that are spread through the air or by droplets.
- affect** The outward expression of a person's inner feelings (happy, sad, angry, fearful, withdrawn).
- afterload** The pressure in the aorta against which the left ventricle must pump blood; increasing this pressure can decrease cardiac output.
- aging** The process by which the temporary bond between the organophosphate and acetylcholinesterase undergoes hydrolysis, resulting in a permanent covalent bond.
- agitated delirium** An acute confrontational state characterized by global impairment of thinking, perception, judgment, and memory; also called excited delirium or exhaustive mania.
- agonal gasps** Occasional gasps that are ineffective attempts at breathing, occurring after the heart has stopped.
- agonist** A substance that mimics the actions of a specific neurotransmitter or hormone by binding to the specific receptor of the naturally occurring substance.
- agoraphobia** Literally, "fear of the marketplace"; fear of entering a public place from which escape may be impeded.
- agranulocytes** Leukocytes that lack granules.
- air ambulances** Fixed-wing aircraft (airplanes) and rotary-wing aircraft (helicopters) that have been modified for emergency medical care; used to evacuate and transport patients with life-threatening injuries to treatment facilities.
- air embolism** The presence of air in the venous circulation, which forms a gas bubble that can block the outflow of blood from the right ventricle to the lung; can lead to cardiac arrest, shock, or other life-threatening complications.
- air embolus** The presence of air in the veins, which can result in cardiac arrest if it enters the heart.
- airborne transmission** The spread of an infectious agent via droplets or dust.
- airway** The upper airway tract or the passage above the larynx, which includes the nose, mouth, and throat, and the lower airway, which includes the trachea and lungs. Also used to refer to devices used to open and maintain a patient's airway.
- alcoholic ketoacidosis** The metabolic acidotic state that manifests because of the inadequate nutritional habits associated with chronic alcohol abuse. The liver and body experience inadequate fuel reserves of glycogen and, thus, have to switch to fatty acid metabolism.
- alcoholism** A state of physical and psychological addiction to ethanol.
- alkalosis** A pathologic condition resulting from the accumulation of bases in the body; a decrease in extracellular H^+ ions; a blood pH greater than 7.45.
- allergen** A substance that causes an allergic reaction.
- allergic reaction** The body's exaggerated immune response to an internal or a surface antigen.
- allergy** A hypersensitivity reaction to the presence of an agent (allergen) that is intrinsically harmless.
- alpha cells** Cells located in the islets of Langerhans that secrete glucagon.
- alpha effects** Stimulation of alpha receptors that results in vasoconstriction.
- alpha radiation** A type of energy that is emitted from a strong radiologic source; it is the least harmful penetrating type of radiation and cannot travel more than a few inches or through most objects.
- altered mental status** Any deviation from alert and oriented to person, place, time, and event, or any deviation from a patient's normal baseline mental status; may signal disease in the central nervous system or other contributing factors.

alternative fuel vehicle A vehicle that uses anything other than a petroleum-based motor fuel (gasoline or diesel) to propel a motorized vehicle.

alveolar ducts Ducts formed from division of the respiratory bronchioles in the lower airway; each duct ends in clusters known as alveoli.

alveolar minute volume The volume of air moved through the lungs in 1 minute minus the dead space; calculated by multiplying tidal volume (minus dead space) and respiratory rate.

alveolar ventilation The volume of air that reaches the alveoli. It is determined by subtracting the amount of dead space air from the tidal volume.

alveoli The air sacs of the lungs in which the exchange of oxygen and carbon dioxide takes place.

ambient temperature The temperature of the surrounding environment.

ambulance A specialized vehicle for treating and transporting sick and injured patients.

amenorrhea Absence of menstruation.

American Standard System A safety system for oxygen cylinders larger than size E, designed to prevent the accidental attachment of a regulator to a cylinder containing the wrong type of gas.

Americans With Disabilities Act (ADA) Comprehensive legislation that is designed to protect people with disabilities against discrimination.

amniotic fluid The fluid produced by the filtration of maternal and fetal blood through blood vessels in the placenta and by excretion of fetal urine into the amniotic sac.

amniotic fluid embolism An extremely rare, life-threatening condition that occurs when amniotic fluid and fetal cells enter the pregnant woman's pulmonary and circulatory system through the placenta via the umbilical veins, causing an exaggerated allergic response from the woman's body.

amniotic sac The fluid-filled, baglike membrane in which the fetus develops.

amphetamines A class of drugs that increase alertness and excitation (stimulants); includes methamphetamine (crank or ice), methylenedioxymphetamine (MDA, Adam), and methylenedioxymphetamine (MDMA, Eve, Ecstasy).

ampules Small glass containers that are sealed and the contents sterilized.

amputation An injury in which part of the body is completely severed; complete avulsion.

anaerobic metabolism The metabolism that takes place in the absence of oxygen; the principal product is lactic acid.

analgesics A classification for medications that relieve pain or induce analgesia.

anaphylactic shock Severe shock caused by an allergic reaction; a severe hypersensitivity reaction that involves bronchoconstriction and cardiovascular collapse.

anaphylactoid reaction An extreme allergic response that does not involve IgE antibody mediation. The exact mechanism is unknown, but an anaphylactoid event may occur without the patient being previously exposed to the offending agent.

anaphylaxis An extreme, life-threatening, systemic allergic reaction to foreign protein or other substances, which may include shock and respiratory failure.

anatomic position The position of reference, in which the patient stands facing you, arms at the side, with the palms of the hands facing forward.

anatomy The study of the structure of an organism and its parts.

anemia A lower-than-normal hemoglobin or red blood cell level.

aneurysm A swelling or enlargement of a part of an artery, resulting from weakening of the arterial wall.

angina pectoris Transient (short-lived) chest discomfort caused by partial or temporary blockage of blood flow to the heart muscle.

angioedema Recurrent large areas of subcutaneous edema of sudden onset, often around the eyes and lips and usually disappearing within 24 hours, which is seen mainly in young women, frequently as a result of allergy to food or drugs.

angiogenesis The growth of new blood vessels.

angiotensin-converting enzyme (ACE) inhibitors Medications that suppress the conversion of angiotensin I to angiotensin II.

- angulation** In a fracture, when each end of the fracture is not aligned in a straight line and an angle has formed between them.
- anion** An ion that contains an overall negative charge.
- anisocoria** Uneven pupil size; can be naturally occurring, but also can be a sign of pathology.
- anoxia** An absence of oxygen.
- antagonist** A substance that counteracts the action of something else; a drug of this type has an affinity for a cell receptor and, when it binds to that receptor, the cell is prevented from responding.
- antecubital** The anterior aspect of the elbow.
- anterior** The front surface of the body; the side facing you in the anatomic position.
- anterograde (posttraumatic) amnesia** Inability to remember events after an injury.
- anteroposterior axis** The axis that runs perpendicular to the coronal plane.
- anthrax** A disease caused by deadly bacteria (*Bacillus anthracis*) that lie dormant in a spore (protective shell); the germ is released from the spore when exposed to the optimal temperature and moisture. The routes of entry are inhalation, cutaneous, and gastrointestinal (from consuming food that contains spores).
- antibody** A protein secreted by certain immune cells that bind antigens to make them more visible to the immune system; an immunoglobulin.
- anticholinergic** Of or pertaining to blockage of acetylcholine receptors, resulting in inhibition of transmission of parasympathetic nerve impulses.
- anticoagulant drugs** The medications used to prevent intravascular thrombosis by preventing blood coagulation in the vascular system.
- anticonvulsant medications** The medications used to treat seizures, which are believed to work by inhibiting the influx of sodium into cells.
- Antidote Treatment Nerve Agent Auto-Injector (ATNAA)** The military form of a nerve agent antidote kit containing atropine and pralidoxime chloride; delivered as a single dose through one needle.
- antidysrhythmic medications** The medications used to treat and prevent cardiac rhythm disorders.
- antigen** An agent that, when taken into the body, stimulates the formation of specific protective proteins called antibodies.
- antihypertensives** The medications used to control blood pressure.
- antiplatelet agents** The medications that interfere with the collection of platelets.
- antivenin** A serum that counteracts the effect of venom from an animal or insect.
- antonyms** Pairs of word roots, prefixes, or suffixes that have opposite meanings.
- anuria** A complete halt in the production of urine.
- anus** The outlet of the rectum.
- anxiety disorders** Mental disorders in which the dominant mood is fear and apprehension.
- anxious-avoidant attachment** An insecure attachment observed in infants who are repeatedly rejected. Children develop an isolated lifestyle that does not depend on the support and care of others.
- aorta** The main artery that receives blood from the left ventricle and delivers it to all the other arteries that carry blood to the tissues of the body.
- aortic aneurysm** A weakness in the wall of the aorta that makes it susceptible to rupture.
- aortic arch** One of the three described portions of the aorta; the section of the aorta between the ascending and descending portions that gives rise to the right brachiocephalic (innominate), left common carotid, and left subclavian arteries.
- aortic valve** The one-way, semilunar valve that lies between the left ventricle and the aorta; keeps blood from flowing back into the left ventricle after the left ventricle ejects its blood into the aorta and is one of four heart valves.
- apex (plural apices or apexes)** The pointed extremity of a conical structure.
- Apgar score system** A scoring system for assessing the status of a newborn that assigns a number value to each of the five areas of assessment.
- aphasia** The inability to understand or produce speech.
- apical pulse** Obtained by auscultating heart tones over the chest with a stethoscope.

aplastic crisis A condition in which the body stops producing red blood cells; typically caused by infection.

apnea Absence of breathing; periods of not breathing.

apneic oxygenation A technique in which oxygen administered via a high-flow nasal cannula is left in place during an intubation attempt, allowing for continuous oxygen delivery into the airways during all phases of the procedure.

apoptosis Normal, genetically programmed cell death.

appendicitis Inflammation of the appendix.

appendicular skeleton The portion of the skeletal system that comprises the arms, legs, pelvis, and shoulder girdle.

appendix A small tubular structure that is attached to the lower border of the cecum in the lower right quadrant of the abdomen.

applied ethics The manner in which principles of ethics are incorporated into professional conduct.

aqueous humor The clear, watery fluid in the anterior chamber of the globe (eyeball).

arachnoid The middle membrane of the three meninges that enclose the brain and spinal cord.

areolar glands The glands that produce secretions that protect the nipple and areola during nursing.

arterial air embolism Air bubbles in the arterial blood vessels.

arterial rupture The rupture of an artery. Involvement of a cerebral artery may contribute to interruption of cerebral blood flow.

arteries Vessels of the circulatory system that carry oxygenated blood away from the heart.

arterioles The smallest branches of arteries leading to the vast network of capillaries.

arteriosclerosis The thickening of the arterial walls that results in a loss of elasticity and concomitant reduction in blood flow.

articulation A movable joint formed where bones or cartilage come in contact with each other.

artifact A tracing on an electrocardiogram that is the result of interference, such as patient

movement, rather than the heart's electrical activity.

ascending aorta The first of three portions of the aorta; originates from the left ventricle and gives rise to two branches, the right and left main coronary arteries.

ascites The accumulation of serous fluid in the peritoneal cavity, typically signaling liver failure.

aseptic technique A method of cleansing used to prevent contamination of a site when performing an invasive procedure, such as inserting an intravenous line.

aspiration The inhalation of liquid or solid matter into the lungs through the trachea, typically as a result of an incompetent gag reflex or overaggressive resuscitation technique.

assault Unlawfully placing a patient in fear of immediate bodily harm.

asthma A chronic inflammatory lower airway condition resulting in intermittent wheezing and excess mucus production; muscle spasm in the small air passageways and excess mucus result in airway obstruction.

asymmetric chest wall movement Unequal movement of the two sides of the chest; indicates decreased airflow into one lung.

asystole Complete absence of heart electrical activity.

ataxia A staggered walk or gait caused by injury to the brain or spinal cord.

ataxic respirations Irregular, ineffective respirations that may or may not have an identifiable pattern.

atelectasis A condition of airless or collapsed alveoli that causes pulmonary shunting, ventilation/perfusion mismatching, and possibly hypoxemia.

atherosclerosis A disorder in which cholesterol and possibly calcium build up inside the walls of blood vessels, forming plaque, which eventually leads to partial or complete blockage of blood flow; a plaque can become a site where blood clots can form, detach, and travel elsewhere in the circulatory system (embolize); the most common form of arteriosclerosis.

- atlanto-occipital joint** The location where the atlas articulates with the occipital condyles.
- atlas** The first cervical vertebra (C1), which provides support for the head.
- atopic** An allergic tendency.
- atrioventricular (AV) node** The site located in the right atrium adjacent to the septum that is responsible for transiently slowing electrical conduction.
- atrioventricular valves** The two valves through which blood flows from the atria to the ventricles.
- atrium** One of two (right and left) upper chambers of the heart.
- atrophy** A decrease in cell size as a result of a loss of subcellular components.
- auditory ossicles** The bones that function in hearing and are located deep within cavities of the temporal bone.
- aura** Sensations experienced before an attack occurs; common in seizures and migraine headaches.
- auscultation** A method of listening to sounds within an organ with a stethoscope.
- autism spectrum disorder (ASD)** A group of complex disorders of brain development, characterized by impairment of social interaction; may include severe behavioral problems, repetitive motor activities, and impairment in verbal and nonverbal skills.
- autoantibodies** Antibodies directed against the person's own proteins.
- autoimmunity** The production of antibodies or T cells that work against the tissues of a person's body, producing autoimmune disease or a hypersensitivity reaction.
- automated external defibrillator (AED)** A device that detects treatable life-threatening cardiac dysrhythmias (ventricular fibrillation and ventricular tachycardia) and delivers the appropriate electrical shock to the patient.
- automaticity** The ability of cardiac cells to generate an impulse to contract even when there is no external nervous stimulus.
- automatic transport ventilator (ATV)** A mechanical ventilator that is used to ventilate intubated patients during transport; has settings for the tidal volume and ventilatory rate.
- autonomic nervous system (ANS)** The part of the nervous system that regulates functions that are not controlled consciously, but rather involuntarily, such as heart rate, blood pressure, digestion, and sweating.
- autoregulation** An increase in mean arterial pressure to compensate for decreased cerebral perfusion pressure; a compensatory physiologic response that occurs in an effort to shunt blood to the brain; manifests clinically as hypertension.
- AVPU scale** A mnemonic to describe the method of assessing the level of consciousness by determining whether the patient is Awake and alert, responsive to Verbal stimuli or Pain, or Unresponsive; used principally early in the assessment process.
- avulsion** An injury in which soft tissue is torn completely loose or is hanging as a flap.
- axial skeleton** The part of the skeleton comprising the skull, spinal column, and rib cage.
- axillary vein** The vein that is formed from the combination of the basilic and cephalic veins; it drains into the subclavian vein.
- axis** The second cervical vertebra (C2); the point that allows the head to turn.
- axon** A long, slender extension of a neuron (nerve cell) that conducts electrical impulses away from the neuronal soma.
- backboard** A long, flat board made of rigid rectangular material that is used to provide support to a patient who is suspected of having a hip, pelvic, spinal, or lower extremity injury; also called a long backboard, spine board, trauma board, and longboard.
- bacteria** Single-cell microorganisms that rapidly reproduce by binary fission; some can form spores (encysted variants) when environmental conditions are harsh.
- bacterial vaginosis** An overgrowth of bacteria in the vagina, characterized by itching, burning, or pain, and possibly a "fishy" smelling discharge.
- bag-mask device** A device with a face mask attached to a ventilation bag containing a reservoir

and connected to oxygen; delivers more than 90% supplemental oxygen.

ball-and-socket joint A joint that allows internal and external rotation, as well as bending.

barbiturates Any medications of a group of barbituric acid derivatives that act as central nervous system depressants and are used as sedatives or hypnotics; potent sedative-hypnotics historically used as sleep aids, as antianxiety drugs, and as part of the regimen for seizure control.

bariatrics A branch of medicine concerned with the management (prevention or control) of obesity and allied diseases.

barometric energy The energy that results from sudden changes in pressure as may occur in a diving accident or sudden decompression in an airplane.

baroreceptors Receptors in the blood vessels, kidneys, brain, and heart that respond to changes in pressure in the heart or main arteries to help maintain homeostasis.

barotrauma Results from a pressure imbalance between gas-filled spaces inside the body and the external atmosphere.

barrier device A protective item, such as a pocket mask with a valve, that limits exposure to a patient's body fluids.

basal ganglia Structures located deep within the cerebrum, diencephalon, and midbrain that have an important role in coordination of motor movements and posture.

base A substance that decreases the concentration of hydrogen ions.

base station Any radio hardware containing a transmitter and receiver that is located in a fixed place.

basic life support (BLS) Noninvasive emergency life-saving care used to treat medical conditions, including airway obstruction, respiratory arrest, and cardiac arrest.

basilar skull fracture An injury that usually occurs following diffuse impact to the head (such as in falls, motor vehicle crashes); generally results from extension of a linear fracture to the base of the skull and can be difficult to diagnose with a radiograph, requiring computed tomography.

basilic vein One of the two major veins of the arm; it combines with the cephalic vein to form the axillary vein.

basket stretcher A rigid stretcher commonly used in technical and water rescues that surrounds and supports the patient yet allows water to drain through holes in the bottom; also called a Stokes litter.

basophils White blood cells that work to produce chemical mediators during an immune response.

battery Unlawfully touching a patient or providing emergency medical care without consent.

Battle sign Bruising behind an ear over the mastoid process that may indicate a skull fracture.

behavior How a person functions or acts in response to the environment.

behavioral crisis The point at which a person's reactions to events interfere with activities of daily living; a behavioral crisis becomes a psychiatric emergency when it causes a major life interruption, such as attempted suicide.

bends Common name for decompression sickness.

benign prostate hypertrophy (BPH) Age-related nonmalignant (noncancerous) enlargement of the prostate gland.

benzodiazepines Sedative-hypnotic drugs that provide muscle relaxation and mild sedation, commonly used to treat anxiety, seizures, and alcohol withdrawal; includes drugs such as diazepam (Valium) and midazolam (Versed).

beta-blocker A common class of cardiac drugs that blocks beta effects, causing a decrease in the workload of the heart by reducing the speed of contraction, as well as reducing blood pressure.

beta cells Cells located in the islets of Langerhans that secrete insulin.

beta effects Stimulation of beta receptors that results in inotropic, dromotropic, and chronotropic states.

beta radiation A type of energy that is emitted from a strong radiologic source; is slightly more penetrating than alpha radiation and requires a layer of clothing to stop it.

biceps The large muscle that covers the front of the humerus.

- bilateral** In anatomy, a body part or condition that appears on both sides of the midline.
- bile ducts** The ducts that convey bile between the liver and the intestine.
- bilevel positive airway pressure (BPAP)** A form of noninvasive positive-pressure ventilation that delivers two pressures (a higher inspiratory positive airway pressure and a lower expiratory positive airway pressure).
- bilirubin** A waste product of red blood cell destruction that undergoes further metabolism in the liver.
- bills of lading** The shipping papers used for transport of chemicals over roads and highways; also referred to as freight bills.
- bioavailability** The rate at and extent to which an active drug enters the general circulation, permitting access to the site of action.
- bioethics** The study of ethics related to issues that arise in health care.
- Biot respirations** Characterized by an irregular rate, pattern, and volume of breathing with intermittent periods of apnea; also called ataxic respirations.
- biotransformation** The chemical alteration that a substance undergoes in the body.
- bipolar mood disorder** A disorder in which a person alternates between mania and depression.
- birth canal** The vagina and cervix.
- blanching** Turning white.
- blast injuries** Injuries resulting from explosions; possible injuries include internal injuries resulting from the pressure wave, penetrating trauma from shrapnel or from being thrown, blunt trauma from being thrown, and burns.
- blast lung** A severe pulmonary contusion, bleeding, or swelling with damage to the blood vessels and alveoli, or a combination of any or all of these.
- blind spots** Areas of the road that are blocked from the driver's sight by their own vehicle or mirrors.
- blood** The fluid that is pumped by the heart through the arteries, veins, and capillaries and consists of plasma and formed elements or cells, such as red blood cells, white blood cells, and platelets.
- blood pressure** The pressure that the blood exerts against the walls of the arteries as it passes through them.
- bloodborne pathogens** Pathogenic microorganisms that are present in human blood and can cause disease in humans. These pathogens include, but are not limited to, hepatitis B virus and human immunodeficiency virus (HIV).
- blow-by oxygen** A method of delivering oxygen by holding a face mask or similar device near the infant or child's face; used when a nonrebreathing mask is not tolerated.
- blowout fracture** A fracture of the orbit or of the bones that support the floor of the orbit.
- blunt trauma** Result of force (or energy transmission) to impact on the body that causes injury without penetrating soft tissues or internal organs and cavities.
- B-NICE** A mnemonic to recall the types of weapons of mass destruction Biologic, Nuclear, Incendiary, Chemical, and Explosive; see also *CBRNE*.
- Boerhaave syndrome** A tear in the esophagus that extends entirely through the esophageal wall, creating a hole; caused by forceful vomiting.
- bolus** A term used to describe "in one mass"; in medication administration, a single dose given by the intravenous route; may be a small or large quantity of the drug.
- bonding** The formation of a close, personal relationship.
- Bone Injection Gun (BIG)** A spring-loaded device that is used for inserting an intraosseous needle into the proximal tibia in adult and pediatric patients.
- bone marrow** A substance that manufactures most red blood cells.
- botulinum** Produced by bacteria; when introduced into the body, this most potent of neurotoxins affects the ability of the nervous system to function and causes botulism.
- botulism** Poisoning characterized by severe muscle paralysis and usually caused by eating food containing botulinum toxin.
- Bourdon-gauge flowmeter** An oxygen flowmeter that is commonly used because it is not affected by gravity and can be placed in any position.

brachial artery The major vessel in the upper extremity that supplies blood to the arm.

bradycardia A slow heart rate; less than 60 beats/min in adults; less than 80 beats/min in children; and less than 100 beats/min in infants.

bradypnea Slow respiratory rate; ominous sign in a child; indicates impending respiratory arrest.

brain The controlling organ of the body and center of consciousness; functions include perception, control of reactions to the environment, emotional responses, and judgment.

brainstem The area of the brain between the spinal cord and cerebrum, surrounded by the cerebellum; controls functions that are necessary for life, such as respiration and cardiac system functions.

Braxton-Hicks contractions Irregularly spaced contractions that are more uncomfortable than painful and that do not increase in frequency or otherwise follow the course of true labor contractions; also known as false labor.

breach of confidentiality Disclosure of medical information without proper authorization.

breach of duty Occurs when a person accused of negligence fails to act as another person with similar training would act under the same or similar circumstances.

breath sounds An indication of air movement in the lungs, usually assessed with a stethoscope.

breath-holding syncope Loss of consciousness caused by a decreased breathing stimulus.

breech presentation A type of abnormal delivery in which the buttocks emerge first.

brief resolved unexplained event (BRUE) An event that causes unresponsiveness, cyanosis, and apnea in an infant, who then resumes breathing with stimulation.

bronchial breath sounds Normal breath sounds made by air moving through the bronchi.

bronchioles Fine subdivisions of the bronchi made of smooth muscle that give rise to the alveolar ducts.

bronchiolitis Inflammation of the bronchioles that usually occurs in children younger than 2 years and is often caused by the respiratory syncytial virus.

bronchospasm Constriction of the airway passages of the lungs that accompanies muscle spasms.

bronchovesicular sounds Soft, breezy, and low-pitched normal breath sounds found at the mid-clavicular line.

bruit An abnormal “whooshing” sound indicating turbulent blood flow within a blood vessel.

buboes Enlarged lymph nodes (up to the size of a tennis ball) that are characteristic in people infected with the bubonic plague.

bubonic plague Bacterial infection that affects the lymphatic system; it is transmitted by infected rodents and fleas and characterized by acute malaise, fever, and the formation of tender, enlarged, inflamed lymph nodes that appear as lesions. Also called the Black Death.

buccal A medication route in which the medication is placed between the cheek and gums, where it is absorbed into the bloodstream.

buddy splinting Securing an injured finger or toe to an adjacent uninjured one to allow the intact digit to act as a splint.

buffer A substance or group of substances that controls the hydrogen levels in a solution.

buffer system Fast-acting defenses for acid-base changes, providing almost immediate protection against changes in the hydrogen ion concentration of extracellular fluid.

bulk storage containers Any container other than nonbulk storage containers, such as fixed tanks, highway cargo tanks, rail tank cars, totes, and intermodal tanks. These are typically found in manufacturing facilities and are often surrounded by a secondary containment system to help control an accidental release.

bundle of His Part of the conduction system of the heart; a continuation of the atrioventricular node.

burnout A state of exhaustion of physical or emotional strength, which may be a consequence of chronic, unrelieved stress.

burns Injuries in which the soft tissue receives more energy than it can absorb without injury, from thermal heat, frictional heat, toxic chemicals, electricity, or nuclear radiation.

- bursa** A small fluid-filled sac located between a tendon and a bone that cushions and protects the joint.
- butterfly catheters** Rigid, hollow, venous cannulation devices identified by plastic “wings” that act as anchoring points for securing the catheter.
- calcitonin** A hormone produced by the parafollicular cells of the thyroid gland that is important in the regulation of calcium levels in the body.
- calcium channel blockers** The medications that suppress dysrhythmias, provide more oxygen to the heart via coronary artery dilation, and reduce peripheral vascular resistance.
- cancellous bone** A type of bone that consists of a lacy network of bony rods called trabeculae.
- cannulation** The insertion of a hollow tube into a vein to allow for fluid flow.
- capillaries** Microscopic, thin-walled blood vessels between the arterioles and venules through which oxygen, carbon dioxide, nutrients, and waste products are exchanged between body tissues and the blood.
- capillary beds** The terminal ends of the vascular system where fluids, food, and wastes are exchanged between the vascular system and the cells of the body.
- capillary refill** A test that evaluates distal circulatory system function by squeezing (blanching) blood from an area such as a nail bed and watching the speed of its return after releasing the pressure.
- capillary refill time** The amount of time that it takes for blood to return to the capillary bed after applying pressure to the skin or nail bed; indicates the status of end-organ perfusion; reliable in children younger than 6 years.
- capnographer** A device that attaches between the endotracheal tube and ventilation device; provides graphic information about the presence of exhaled carbon dioxide.
- capnography** A noninvasive method that can quickly and efficiently provide information on a patient’s ventilatory status, circulation, and metabolism; effectively measures the concentration of carbon dioxide in expired air over time.
- capnometer** A device that performs the same function and attaches in the same way as a capnographer but provides a digital reading of the exhaled carbon dioxide.
- capnometry** The use of a capnometer, a device that measures the amount of expired carbon dioxide.
- carbon dioxide (CO₂)** A component that typically makes up 0.3% of air at sea level; also a waste product exhaled during expiration by the respiratory system.
- carbon dioxide retention** A condition characterized by a chronically high level of carbon dioxide in blood as the result of a respiratory disease.
- carbon monoxide (CO)** An odorless, highly poisonous gas that results from the incomplete oxidation of carbon during combustion.
- carboys** Glass, plastic, or steel containers, ranging in volume from 5 to 15 gallons (19 to 57 L).
- cardiac arrest** A state in which the heart fails to generate an effective and detectable blood flow; pulses are not palpable in cardiac arrest, even if muscular and electrical activity continues in the heart.
- cardiac cycle** The repetitive pumping process that begins with the onset of cardiac muscle contraction and ends just before the beginning of the next contraction.
- cardiac glycosides** A classification of medications that naturally occur in plant substances and that block certain ionic pumps in the membranes of heart cells, which indirectly increases calcium concentrations; an example is digoxin.
- cardiac muscle** The heart muscle.
- cardiac output (CO)** The amount of blood pumped by the heart per minute; calculated by multiplying the stroke volume by the pulse rate per minute.
- cardiac tamponade** Compression of the heart caused by a buildup of blood or other fluid in the pericardial sac.
- cardiogenic shock** Shock caused by inadequate function of the heart, or pump failure; caused by loss of 40% or more of the functioning myocardium; the heart is no longer able to circulate sufficient blood to maintain adequate oxygen delivery; can be a severe complication of a large acute myocardial infarction, as well as other conditions.

cardiopulmonary resuscitation (CPR) The combination of chest compressions and rescue breathing used to establish adequate ventilation and circulation in a patient who is not breathing and has no pulse.

carina Point at which the trachea bifurcates (divides) into the left and right main stem bronchi.

carotid artery The major artery that supplies blood to the head and brain.

carpometacarpal joint The joint between the wrist and the metacarpal bones; the thumb joint.

carpopedal spasm A contorted position of the hand or foot in which the fingers or toes flex in a clawlike manner; may result from hyperventilation or hypocalcemia.

cartilage The support structure of the skeletal system that provides cushioning between bones; also forms the nasal septum and portions of the outer ear.

casualty collection area An area set up by physicians, nurses, and other hospital staff near a major disaster or mass-casualty incident scene where patients can receive further triage and medical care.

cataract Clouding of the lens of the eye or its surrounding transparent membrane.

catecholamines Hormones produced by the adrenal medulla (epinephrine and norepinephrine) that assist the body in coping with physical and emotional stress by increasing the heart and respiratory rates and the blood pressure.

catheter A flexible, hollow structure that delivers fluid.

catheter shear A free-floating segment of a catheter in the circulatory system, created if the needle slices through the catheter while it is being inserted.

cation An ion that contains an overall positive charge.

cauda equina The collection of nerves at the end of the spinal cord; consists of the second through fifth lumbar nerve pairs, the first through fifth sacral nerve pairs, and the coccygeal nerve.

caustics Chemicals that are acids or alkalis; they cause direct chemical injury to the tissues they contact.

cavitation Formation of a temporary cavity that is produced by stretching of the tissue surrounding the point of impact—for example, when speed causes a bullet to generate pressure waves, which cause damage distant from the bullet's path.

CBRNE A mnemonic used to recall the types of weapons of mass destruction Chemical, Biologic, Radiologic, Nuclear, and Explosive; see also *B-NICE*.

cecum The first part of the large intestine, into which the ileum opens.

cell membrane The cell wall; the cell membrane is selectively permeable.

cell phone A low-power portable radio that communicates through an interconnected series of repeater stations called cells.

cell-mediated immunity The immune process by which T-cell lymphocytes recognize antigens and then secrete cytokines (specifically lymphokines) that attract other cells or stimulate the production of cytotoxic cells that kill the infected cells.

cellular immunity The immunity provided by special white blood cells called T cells that attack and destroy invaders.

cellular perfusion The ability of a cell to take in oxygen and remove carbon dioxide.

cellular respiration A biochemical process resulting in the production of energy in the form of adenosine triphosphate.

Centers for Disease Control and Prevention (CDC) The primary federal agency that conducts and supports public health activities in the United States. The CDC is part of the US Department of Health and Human Services.

central cyanosis Cyanosis to the newborn's face and trunk; indicates hypoxia.

central nervous system (CNS) The brain and spinal cord.

central neurogenic hyperventilation Deep, rapid respirations; similar to Kussmaul, but without an acetone breath odor; commonly seen following brainstem injury.

central pulses Pulses that are closest to the core (central) part of the body where the vital organs are located.

- central shock** A type of shock caused by central pump failure, including cardiogenic shock and obstructive shock.
- central vision** The visualization of objects directly in front of you.
- cerebellum** One of the three major subdivisions of the brain, sometimes called the athlete's brain; coordinates the various activities of the brain, particularly fine body movements.
- cerebral contusion** A focal brain injury in which brain tissue is bruised and damaged in a defined area.
- cerebral cortex** The largest portion of the cerebrum; regulates voluntary skeletal movement and a person's level of awareness—a part of consciousness.
- cerebral edema** Swelling of the brain.
- cerebral embolism** Obstruction of a cerebral artery caused by a clot that was formed elsewhere in the body and traveled to the brain.
- cerebral palsy** A group of disorders characterized by poorly controlled body movement.
- cerebral perfusion pressure (CPP)** The pressure of blood flow through the brain; the difference between the mean arterial pressure (MAP) and intracranial pressure (ICP).
- cerebrospinal fluid (CSF)** Fluid produced in the ventricles of the brain that flows in the subarachnoid space and bathes the meninges.
- cerebrovascular accident (CVA)** Interruption of blood flow to the brain that results in the loss of brain function; also referred to as a stroke or brain attack.
- cerebrum** The largest part of the three subdivisions of the brain, sometimes called the gray matter; made up of several lobes that control movement, hearing, balance, speech, visual perception, emotions, and personality.
- certification** A process in which a person, an institution, or a program is evaluated and recognized as meeting certain predetermined standards to provide safe and ethical patient care.
- cervical spine** The portion of the spinal column consisting of the first seven vertebrae that lie in the neck.
- cervix** The lower third, or neck, of the uterus.
- chancroid** A highly contagious sexually transmitted infection caused by the bacteria *Haemophilus ducreyi*, which causes painful sores (ulcers), usually of the genitals.
- channel** An assigned frequency or frequencies that are used to carry voice and/or data communications.
- chassis** The structural framework of the ambulance.
- chassis set** The transfer of weight (center of mass) to different points on the chassis.
- chemical energy** The energy released as a result of a chemical reaction.
- chemical mediators** Chemicals that work to cause the immune or allergic response—for example, histamine and leukotrienes.
- chemical name** Precise description of a drug's chemical composition and molecular structure.
- chemical suicide** A method of suicide that involves mixing certain household chemicals in an enclosed space to create toxic gases, such as hydrogen sulfide and hydrogen cyanide, as the chemicals combine; also called detergent suicide.
- Chemical Transportation Emergency Center (CHEMTREC)** An agency that assists emergency responders in identifying and handling hazardous materials incidents.
- chemoreceptors** Receptors in the blood vessels, kidneys, brain, and heart that respond to changes in chemical composition of the blood to help maintain homeostasis.
- chemotaxis** Components of the activated complement system that attract leukocytes from the circulation to help fight infections.
- chemotaxis** The movement of additional white blood cells to an area of inflammation in response to the release of chemical mediators, such as neutrophils, injured tissue, and monocytes.
- chest compression fraction** The total percentage of time during a resuscitation attempt in which active chest compressions are being performed.
- Cheyne-Stokes respirations** The respirations that are fast and then become slow, with intervening periods of apnea; commonly seen following brainstem injury.

chief complaint The reason a patient called for emergency medical services; also, the patient's response to questions such as "What's wrong?" or "What happened?"

child abuse Any improper or excessive action that injures or otherwise harms a child or infant; includes physical abuse, sexual abuse, neglect, and emotional abuse.

chlamydia A sexually transmitted infection caused by the bacterium *Chlamydia trachomatis*.

chlorine (Cl) The first chemical agent ever used in warfare; it has a distinct odor of bleach and creates a green haze when released as a gas. Initially it produces upper airway irritation and a choking sensation.

cholecystitis Inflammation of the gallbladder.

cholinergic Fibers in the parasympathetic nervous system that release a chemical called acetylcholine.

chordae tendineae Thin bands of fibrous tissue that attach to the valves in the heart and prevent them from inverting, preventing regurgitation of blood through the valves from the ventricles to the atria.

choroid plexus Specialized cells within hollow areas in the ventricles of the brain that produce cerebrospinal fluid.

chromosomes Structures formed from condensed fibers and protein of deoxyribonucleic acid; they are threadlike and are contained within the nucleus of the cells.

chronic bronchitis Irritation and inflammation of the major lung passageways, from either infectious disease or irritants such as smoke.

chronic hypertension A blood pressure that is equal to or greater than 130/80 mm Hg, which exists prior to pregnancy, occurs before the 20th week of pregnancy, or persists postpartum.

chronic kidney disease Progressive and irreversible inadequate kidney function as a result of permanent loss of nephrons.

chronic obstructive pulmonary disease (COPD) A slow, degenerative process that causes destructive changes in the alveoli and bronchioles in the lungs.

chronotropic Affecting the rate of contraction of the heart.

chronotropic effect Affecting the heart's rate of contraction.

chronotropic state Related to the control of the heart's rate of contraction.

chyme The name of the substance that leaves the stomach; a combination of eaten foods with added stomach acids.

circulatory system The complex arrangement of connected tubes, including the arteries, arterioles, capillaries, venules, and veins, that moves blood, oxygen, nutrients, carbon dioxide, and cellular waste throughout the body.

circumflex coronary artery One of the two branches of the left main coronary artery.

circumstantial thinking A situation in which the patient includes many irrelevant details in an account of things.

civil lawsuit An action instituted by a person or entity against another person or entity.

clavicle The collarbone; it is lateral to the sternum and anterior to the scapula.

cleaning The process of removing dirt, dust, blood, or other visible contaminants from a surface.

clitoris Located in the anterior margin of the vestibule and partially hidden by the labia minora, it contains erectile tissue that becomes engorged with blood as a result of sexual excitement.

clonic phase Seizure movement marked by repetitive muscle contractions and relaxations in rapid succession.

closed abdominal injury An injury in which there is soft-tissue damage inside the body but the skin remains intact.

closed chest injury An injury to the chest in which the skin is not broken, usually from blunt trauma.

closed fracture A fracture in which the skin is not broken.

closed head injury An injury in which the brain has been injured but the skin has not been broken and there is no bleeding.

closed incident An incident that is contained; all casualties are accounted for.

- closed injury** An injury in which damage occurs beneath the skin or mucous membrane but the surface remains intact.
- closed-ended questions** Questions that can be answered in short or single-word responses.
- clotting factors** Substances in the blood that are necessary for clotting; also called coagulation factors.
- coagulation system** The system that forms blood clots in the body and facilitates repairs to the vascular tree.
- coagulopathy** Any type of bleeding disorder that interferes with the activation or continuation of the clotting cascade or hemostasis.
- Cobra perilaryngeal airway (CobraPLA)** A supra-glottic airway device with a shape that allows the device to slide easily along the hard palate and to hold the soft tissue away from the laryngeal inlet.
- coccyx** The last three to five vertebrae of the spine; the tailbone.
- coefficient of friction** A measure of the grip of the tires on the road.
- cold zone** A safe area at a hazardous materials incident for the agencies involved in the operations. The incident commander, the command post, EMS providers, and other support functions necessary to control the incident should be located in this zone. Also referred to as the clean zone or the support zone.
- colic** Acute, intermittent, cramping abdominal pain.
- colloid solution** A type of intravenous solution that contains compounds that are too large to pass out of the capillary membranes and therefore remain in the vascular compartment; for example, used to help reduce edema.
- colorimetric carbon dioxide detector** A device that attaches between the endotracheal tube and ventilation device; uses special paper that should turn from purple to yellow during exhalation, indicating the presence of exhaled carbon dioxide.
- colorimetric devices** End-tidal carbon dioxide detectors that use a chemical reaction to detect the amount of carbon dioxide present in expired gases.
- colostomy** The surgical procedure to create an opening (stoma) between the colon and the surface of the body to provide drainage of the bowel.
- coma** A state in which a person does not respond to either verbal or painful stimuli.
- combining form** A word root followed by a vowel.
- combining vowel** The vowel used to combine two word roots or a word root and a prefix or suffix.
- Combitube** A dual-lumen airway device that is inserted blindly; permits ventilation of the patient whether the tube is placed in the esophagus or the trachea.
- command** In incident command, the position or positions that oversee the incident, establish the objectives and priorities, and develop a response plan; functions may include a public information officer, safety officer, and liaison officer.
- command post** The designated field command center where the incident commander and support staff are located.
- common cold** A viral infection usually associated with swollen nasal mucous membranes and the production of fluid from the sinuses.
- commotio cordis** An event in which an often fatal cardiac dysrhythmia is produced by a sudden blow to the thoracic cavity.
- communicable disease** A disease that can be spread from one person or species to another.
- communication** The transmission of information to another person—verbally or through body language.
- community paramedicine** A health care model in which experienced paramedics receive advanced training to allow them to provide additional services in the prehospital environment, such as health evaluations, monitoring of chronic illnesses or conditions, and patient advocacy.
- compartment syndrome** An elevation of pressure within the fascial compartment, characterized by extreme pain, decreased pain sensation, pain on stretching of affected muscles, and decreased power; most frequently seen in fractures below the elbow or knee in children.
- compassion fatigue** A stress disorder characterized by gradual lessening of compassion over time.

compensated shock The early stage of shock, in which the body can still compensate for blood loss; also called nonprogressive shock.

compensatory damages Compensation awarded in a civil lawsuit that is intended to restore the plaintiff to the same condition that the person was in prior to the incident.

competent Able to make rational decisions about personal well-being.

complement system A group of plasma proteins whose function is to do one of three things: attract leukocytes to sites of inflammation, activate leukocytes, and directly destroy cells.

complete abortion The expulsion of all products of conception from the uterus.

complex access Entry that requires special tools and training and includes the use of force.

compound word A word containing more than one word root.

compulsions Repetitive actions carried out to relieve the anxiety of obsessive thoughts.

computer-aided dispatch (CAD) Linked dispatch center computer consoles and vehicle-mounted mobile data terminals in which a computer collects and manages the call information and makes recommendations for which emergency medical services unit is closest based on existing dispatch policy.

concealment The use of objects to limit a person's visibility of you.

concentration The total weight of a drug contained in a specific volume of liquid.

concentration gradient The natural tendency for substances to flow from an area of higher concentration to an area of lower concentration, either within the cell or outside the cell.

concussion A temporary loss or alteration of part or all of the brain's abilities to function without actual physical damage to the brain.

conduction The loss of heat by direct contact (eg, when a body part comes in contact with a colder object).

conduction system A group of complex electrical tissues within the heart that initiate and transmit

stimuli that result in contractions of myocardial tissue.

conductive hearing loss Hearing loss caused by a faulty transmission of sound waves.

conductivity The ability of the cardiac cells to conduct electrical impulses.

confabulation The invention of experiences to cover gaps in memory, seen in patients with certain organic brain syndromes.

conjunctiva The delicate membrane that lines the eyelids and covers the anterior exposed surface of the eye.

conjunctivitis Inflammation of the conjunctiva.

connecting nerves The nerves in the brain and spinal cord that connect the motor and sensory nerves.

Consensus formula A formula that recommends giving 2 to 4 mL of lactated Ringer solution for each kilogram of body weight, multiplied by the percentage of total body surface area burned during the first 24 hours following the burn; one-half of the volume is given in the first 8 hours and the other half in the next 16 hours; sometimes used to calculate fluid needs during lengthy transport times; formerly called the Parkland formula.

consent Permission to render emergency medical care.

contact burn A burn produced by touching a hot object.

contact hazard The danger posed by an agent whose primary route of exposure is through the skin; also called a skin hazard.

contagious An infectious disease that can be transmitted to another; communicable.

container Any vessel or receptacle that holds material, including storage vessels, pipelines, and packaging.

contaminated stick The puncturing of an emergency care provider's skin with a catheter that was used on a patient.

contamination The presence of infectious organisms (pathogens) or foreign bodies such as dirt, gravel, or metal in a wound.

- continuous positive airway pressure (CPAP)** A method of ventilation used primarily in the treatment of critically ill patients with respiratory distress; can prevent the need for endotracheal intubation.
- continuous quality improvement (CQI)** A system of internal and external reviews and audits of all aspects of an emergency medical services system.
- contractility** The strength of heart muscle contraction.
- contraindications** Situations in which a medication should not be given because it would not help or may actually harm a patient.
- contralateral** On the opposite side of the body.
- control zones** Areas at a hazardous materials incident that are designated as hot, warm, or cold, based on safety issues and the degree of hazard found there.
- contusion** A bruise without a break in the skin; ecchymosis.
- convection** The loss of body heat caused by air movement (eg, breeze blowing across the body).
- conventional reasoning** A type of reasoning in which a child looks for approval from peers and society.
- core temperature** The temperature of the central part of the body (eg, the heart, lungs, and vital organs).
- cornea** The transparent tissue layer in front of the pupil and iris of the eye.
- coronal plane** An imaginary plane in which the body is cut into front and back portions.
- coronary arteries** Arteries that arise from the aorta shortly after it leaves the left ventricle and supply the heart with oxygen and nutrients.
- coronary artery disease** The condition that results when atherosclerosis or arteriosclerosis is present in the arterial walls.
- coronary sinus** The end of the great cardiac vein that collects blood returning from the walls of the heart.
- corpus luteum** The remnants of an unfertilized ovum that are sloughed during menstruation.
- corticosteroids** Any of several steroids secreted by the adrenal gland.
- cortisol** A hormone that stimulates most body cells to increase their energy production.
- coup-contrecoup** Occurs when the brain continues its forward motion and strikes the inside of the skull, resulting in a compression injury to the anterior portion of the brain and stretching of the posterior portion.
- coup-contrecoup injury** Dual impacting of the brain into the skull; coup injury occurs at the point of impact; contrecoup injury occurs on the opposite side of impact, as the brain rebounds.
- cover** The tactical use of an impenetrable barrier for protection.
- covert** An act in which the public safety community generally has no prior knowledge of the time, location, or nature of the attack.
- CPR board** A device that provides a firm surface under the patient's torso.
- crackles** Crackling, moist breath sounds signaling fluid in the smaller air passages of the lungs; formerly called rales.
- cranial nerves** The 12 pairs of nerves that arise from the base of the brain.
- cranial vault** The bones that encase and protect the brain, including the parietal, temporal, frontal, occipital, sphenoid, and ethmoid bones.
- craniofacial disjunction** A Le Fort III fracture; involves a fracture of all of the midfacial bones, thereby separating the entire midface from the cranium.
- cranium** The area of the head above the ears and eyes; the skull. The cranium contains the brain.
- credentialing** An established process to determine the qualifications necessary to be allowed to practice a particular profession, or to function as an organization.
- crenation** Shrinkage of a cell that results when too much water leaves the cell through osmosis.
- crepitus** A grating or grinding sensation caused by fractured bone ends or joints rubbing together; also, air bubbles under the skin that produce a crackling sound or crinkly feeling.
- crew resource management (CRM)** A way for team members to work together with the team leader to develop and maintain a shared understanding

of the emergency situation; to collaborate and communicate, fulfill their roles and responsibilities, and achieve the shared goal of the best possible patient outcome.

cribriform plate A horizontal bone perforated with numerous foramina for the passage of the olfactory nerve filaments from the nasal cavity.

cricoid cartilage A firm ridge of cartilage that forms the lower part of the larynx.

cricothyroid membrane A thin sheet of fascia that connects the thyroid and cricoid cartilages that make up the larynx.

criminal prosecution An action instituted by the government against a person for violation of criminal law.

crista galli A prominent bony ridge in the center of the anterior fossa to which the meninges are attached.

critical incident stress management (CISM) A process that confronts the responses to critical incidents and defuses them, directing the emergency services personnel toward physical and emotional equilibrium.

Crohn disease Inflammation of the ileum and possibly other portions of the gastrointestinal tract, in which the immune system attacks portions of the intestinal walls, causing them to become scarred, narrowed, stiff, and weakened.

cross section The product of slicing an object crosswise, perpendicular to its long axis.

cross-contamination Occurs when a person is contaminated by an agent as a result of coming in contact with another contaminated person.

cross-tolerance A tolerance to a particular drug that crosses over to other drugs in the same class.

croup An infectious disease of the upper respiratory system, usually caused by a virus, that may cause partial airway obstruction and is characterized by a barking cough; usually seen in children; also referred to as laryngotracheobronchitis.

crowning The appearance of the newborn's head at the vaginal opening during labor.

crush syndrome Significant metabolic derangement that develops when crushed extremities or body parts remain trapped for prolonged periods; it can lead to renal failure and death.

crystalloid solution A type of intravenous solution that contains compounds that quickly disassociate in solution and can cross membranes; considered the best choice for prehospital care of injured patients who need fluids to replace lost body fluid.

Cullen sign A black-and-blue discoloration (ecchymosis) in the umbilical region caused by peritoneal bleeding.

cultural imposition When individuals impose their beliefs, values, and practices on another because they believe their ideals are superior.

cumulative effect Action of increased intensity after administration of several doses of a drug.

cumulative stress reactions Exposure to prolonged or excessive stress.

Cushing triad Hypertension (with a widening pulse pressure), bradycardia, and irregular respirations; classic trio of findings associated with increased intracranial pressure.

cushion of safety A defensive driving technique used to keep a safe distance between the ambulance and other vehicles on any side of the ambulance.

cyanide A colorless gas that affects the body's ability to use oxygen; it has an odor similar to almonds. The effects begin on the cellular level and are rapidly seen at the organ and system levels.

cyanosis A blue-gray skin color that is caused by a reduced level of oxygen in the blood.

cylinders Portable, compressed-gas containers used to hold liquids and gases such as nitrogen, argon, helium, and oxygen. They have a range of sizes and internal pressures.

cystic fibrosis (CF) A genetic disorder of the endocrine system that makes it difficult for chloride to move through the cells; characterized by increased production of mucus in the lungs and digestive system; also called mucoviscidosis.

cystitis Another name for urinary tract infection.

cytokines The products of cells that affect the function of other cells.

cytokinesis The division of the cytoplasm of a cell.

cytomegalovirus (CMV) A herpesvirus that can produce the symptoms of prolonged high fever,

chills, headache, malaise, extreme fatigue, and an enlarged spleen.

D₅W An intravenous solution made up of 5% dextrose in water.

damages Compensation for injury; awarded by a court.

danger zone An area where people can be exposed to hazards such as electric wires, sharp metal edges, broken glass, toxic substances, radiation, or ignition or explosion of hazardous materials.

DCAP-BTLS A mnemonic for assessment in which each area of the body is evaluated for Deformities, Contusions, Abrasions, Punctures/penetrations, Burns, Tenderness, Lacerations, and Swelling.

dead space Any portion of the airway that does not contain air and cannot participate in gas exchange, such as the trachea and bronchi.

decay A natural process in which a material that is unstable attempts to stabilize itself by changing its structure.

deceleration The slowing of an object.

decerebrate (extensor) posturing A posture characterized by extension of the arms and legs, in which the arms rotate in a palms-down manner and the toes point; indicates pressure on the brainstem and may appear in patients with severe brain trauma.

decision-making capacity The ability to understand and process information and make a choice regarding appropriate medical care.

decompensated shock The late stage of shock when blood pressure is falling; also called progressive shock.

decompression sickness A painful condition seen in divers who ascend too quickly, in which gas, especially nitrogen, forms bubbles in blood vessels and other tissues; also called the bends.

decontaminated To have removed or neutralized radiation, chemical, or other hazardous material from clothing, equipment, vehicles, and personnel.

decontamination The process of removing or neutralizing and properly disposing of hazardous materials from equipment, patients, and responders.

decontamination area The designated area in a hazardous materials incident where all patients and responders must be decontaminated before going to another area.

decorticate (flexor) posturing A posture characterized by flexion of the arms and extension of the legs, in which the arms flex and curl toward the chest, the wrists flex, and the toes point; indicates pressure on the brainstem and may appear in patients with severe brain trauma.

decubitus ulcers Ulcers that occur when pressure is applied to body tissue, resulting in a lack of perfusion and ultimately necrosis.

dedicated line A special telephone line that is used for specific point-to-point communications; also known as a hotline.

deep Farther inside the body and away from the skin.

deep fascia A dense layer of fibrous tissue below the subcutaneous tissue; composed of tough bands of tissue that surround muscles and other internal structures.

deep vein thrombosis (DVT) The formation of a blood clot within the larger veins of an extremity, typically following a period of prolonged immobilization.

defamation The communication of false information about a person that is damaging to that person's reputation or standing in the community.

defendant In a civil lawsuit, the person against whom a legal action is brought.

defibrillate To shock a fibrillating (chaotically beating) heart with specialized electrical current in an attempt to restore a normal rhythmic beat.

delayed stress reactions Reactions to stress that occur after a stressful situation.

delirium An acute change in mental status marked by the inability to focus, think logically, and maintain attention.

delirium tremens (DTs) A severe withdrawal syndrome seen in people with alcoholism who are deprived of ethyl alcohol, which is characterized by restlessness, fever, sweating, disorientation, agitation, and seizures; it can be fatal if untreated.

delusions Fixed beliefs that are not shared by others of a person's culture or background and that cannot be changed by reasonable argument; false beliefs.

dementia The slow onset of progressive disorientation, shortened attention span, and loss of cognitive function.

demobilization The process of directing responders to return to their facilities when their work at an incident has finished.

denitrogenation The process of replacing nitrogen in the lungs with oxygen to maintain a normal oxygen saturation level during advanced airway management.

dependent edema Swelling in the part of the body closest to the ground, caused by collection of fluid in the tissues; a possible sign of heart failure.

dependent lividity Blood settling to the lowest point of the body, causing discoloration of the skin; a definitive sign of death.

dependent living A type of care in which a person receives assistance based on the person's needs or restrictions; can range from the least restrictive retirement community to the structured skilled nursing facility and dementia/ Alzheimer disease specialty care facilities. Sometimes known as residential.

depolarization The rapid movement of electrolytes across a cell membrane that changes the cell's overall charge. This rapid shifting of electrolytes and cellular charges is the main catalyst for muscle contractions and neural transmissions.

depositions Verbal statements from parties and witnesses taken under oath.

depressants Agents used to slow brain activity.

depressed skull fracture A type of skull fracture that results from high-energy direct trauma to a small surface area of the head with a blunt object (such as a baseball bat to the head); commonly results in bony fragments being driven into the brain, causing injury.

depression A mental health disorder characterized by a persistent mood of sadness, despair, and discouragement.

dermatome An area of the skin supplied by a specific sensory spinal nerve.

dermis The inner layer of the skin, containing hair follicles, sweat glands, sebaceous glands, nerve endings, and blood vessels.

descending aorta One of the three portions of the aorta, it is the longest portion and extends through the thorax and abdomen into the pelvis.

designated officer The person in the department who is charged with the responsibility of managing exposures and infection control issues.

desired dose The amount of a drug that the physician orders for a patient; the drug order.

devascularization The loss of perfusion to a part of the body.

developmental disability Insufficient development of the brain, resulting in some level of dysfunction or impairment.

diabetes mellitus A metabolic disorder in which the ability to metabolize carbohydrates (sugars) is impaired due to a lack of insulin.

diabetic ketoacidosis (DKA) A form of acidosis in uncontrolled diabetes in which certain acids accumulate when insulin is not available.

diamond carry A carrying technique in which one provider is located at the head end of the stretcher or backboard, one at the foot end, and one at each side of the patient; each of the two providers at the sides uses one hand to support the stretcher or backboard so that all are able to face forward as they walk.

diapedesis A process whereby leukocytes leave blood vessels to move toward tissue where they are needed most.

diaphoretic Characterized by light or profuse sweating.

diaphragm A muscular dome that forms the undersurface of the thorax, separating the chest from the abdominal cavity. Contraction of the diaphragm (and the chest wall muscles) brings air into the lungs. Relaxation allows air to be expelled from the lungs.

diaphysis The shaft of a long bone.

diastole The relaxation phase of the cardiac cycle, when the ventricles are filling with blood.

diastolic pressure The pressure that remains in the arteries during the relaxing phase of the cycle

of the heart (diastole) when the left ventricle is at rest.

dieffenbachia A common houseplant that resembles “elephant ears”; its ingestion leads to burns of the mouth and tongue and, possibly, paralysis of the vocal cords and nausea and vomiting. In severe cases, ingestion may cause edema of the tongue and larynx, leading to airway compromise.

diencephalon Portion of the brain between the brainstem and cerebrum; contains the epithalamus, the thalamus, the hypothalamus, and the subthalamus.

diffuse axonal injury (DAI) Diffuse brain injury that is caused by stretching, shearing, or tearing of nerve fibers with subsequent axonal damage.

diffuse brain injury Any injury that affects the entire brain.

diffuse pain Pain that is not identified as being specific to a single location but is spread out over an area of the body or felt all over the body.

diffusion The movement of solutes (molecules) from an area of higher solute concentration to an area of lower solute concentration.

digestion The processing of food that nourishes the individual cells of the body.

digital radio The transmission of information via radio waves using native digital (computer) data or analog (voice) signals that have been converted to a digital signal and compressed.

diphtheria An infectious disease in which a membrane lining the pharynx is formed that can severely obstruct passage of air into the larynx.

diplopia Double vision.

direct carry method A nonurgent move that is a method for moving a patient from a bed to a stretcher, in which a stretcher is positioned next to the bed and two providers move the patient.

direct contact Exposure to or transmission of a communicable disease from one person to another by physical contact.

direct ground lift A lifting technique that is used for patients who are found lying supine on the ground with no suspected spinal injury.

direct laryngoscopy Visualization of the airway with a laryngoscope.

dirty bomb Any container that is designed to disperse radioactive material; see also *radiologic dispersal device*.

disaster A widespread event that disrupts community resources and functions, in turn threatening public safety, citizens' lives, and property.

discovery The phase of a civil lawsuit where the plaintiff and defense obtain information from each other that will enable the attorneys to have a better understanding of the case and that will assist them in negotiating a possible settlement or in preparing for trial; includes depositions, interrogatories, and demands for production of records.

disease vector An animal that spreads a disease, once infected, to another animal.

disequilibrium syndrome A condition characterized by nausea, vomiting, headache, and confusion, which results when, as a consequence of dialysis, water initially shifts from the bloodstream into the cerebrospinal fluid, mildly increasing intracranial pressure.

disinfection The killing of pathogenic agents by direct application of chemicals.

dislocation Disruption of a joint in which ligaments are damaged and the bone ends are completely displaced.

disorganization A condition in which a person is characterized by uncontrolled and disconnected thought, is usually incoherent or rambling in speech, and may or may not be oriented to person and place.

disorientation A condition in which a person may be confused about their identity, location, and time of day; one of the ways in which various conditions such as schizophrenia or organic brain syndrome may present.

displaced fracture A fracture in which bone fragments are separated from one another and are not in anatomic alignment.

dissecting aneurysm A condition in which the inner layers of an artery, such as the aorta, become separated, allowing blood (at high pressures) to flow between the layers.

disseminated intravascular coagulation (DIC) A condition that begins with widespread activation of the clotting cascade, which depletes the

clotting factors and platelets, and eventually results in uncontrolled hemorrhage.

dissemination The means by which a terrorist will spread an agent, such as by poisoning the water supply or aerosolizing the agent into the air or ventilation system of a building.

dissociative anesthetic agents A category of drugs that cause profound dissociation and general anesthesia, often used as an adjunct to facilitate airway placement in the prehospital environment; includes ketamine.

distal Farther from the trunk and nearer to the free end of the extremity.

distraction The action of pulling the spine along its length.

distributive shock The type of shock caused by widespread dilation of the resistance vessels (small arterioles), the capacitance vessels (small venules), or both.

diuretic medications The medications designed to promote elimination of excess salt and water by the kidneys.

diverticulitis Inflammation of a diverticulum, usually in the colon, creating abdominal discomfort; a *diverticulum* is an abnormal pouch or sac.

diving reflex Slowing of the heart rate caused by submersion in cold water.

do not resuscitate (DNR) order Written documentation by a physician giving permission to medical personnel not to attempt resuscitation in the event of cardiac arrest.

documentation The recorded portion of the AEMT's patient interaction, either written or electronic; it becomes part of the patient's permanent medical record.

domestic terrorism Terrorism that is carried out by people hoping to further ideological causes relevant to the nation in which they are acting.

dorsal The posterior surface of the body, including the back of the hand.

dorsal respiratory group (DRG) A portion of the medulla oblongata where the primary respiratory pacemaker is found.

dorsalis pedis artery The artery on the anterior surface of the foot between the first and second metatarsals.

dose The amount of medication given on the basis of the patient's size and age.

Down syndrome A genetic chromosomal defect that can occur during fetal development and that results in intellectual impairment and certain physical characteristics, such as a round head with a flat occiput and slanted, wide-set eyes.

drag Resistance, such as air, that slows a projectile.

draw sheet method A nonurgent move that is a method for moving a patient from a bed onto a stretcher using a sheet on which the patient is lying.

drip chamber The area of the administration set where fluid accumulates so that the tubing remains filled with fluid.

drip rate Number of drops per minute.

drip set Another name for an administration set.

dromotropic Affecting the velocity of conduction in the heart.

dromotropic effect Affecting the heart's velocity of conduction.

dromotropic state Related to the control of the heart's conduction rate.

drowning The process of experiencing respiratory impairment from submersion or immersion in liquid.

drug abuse Any use of drugs that causes physical, psychological, economic, legal, or social harm to the user or others affected by the user's behavior.

drug addiction A chronic disorder characterized by the compulsive use of a substance that results in physical, psychological, or social harm to the user who continues to use the substance despite the harm.

drug antagonism A decrease in the action of a drug by the administration of another drug.

drug A substance that has some therapeutic effect (such as reducing inflammation, fighting bacteria, or producing euphoria) when given in the appropriate circumstances and in the appropriate dose.

drug dependence A psychological and sometimes physical state resulting from continued use of a substance, characterized by a compulsion to take the drug on a continuous or periodic basis

to experience its effects or to avoid the discomfort of its absence.

drug reconstitution Injecting sterile water (or saline) from one vial into another vial containing a powdered form of the drug.

drugs Chemical agents used in the diagnosis, treatment, and prevention of disease.

drums Barrel-like containers used to store a wide variety of substances, including food-grade materials, corrosives, flammable liquids, and grease. May be constructed of low-carbon steel, polyethylene, cardboard, stainless steel, nickel, or other materials.

ductus arteriosus A small artery that connects the left pulmonary artery to the aorta; diverts blood away from the fetal lungs while in utero.

DuoDote Auto-Injector A nerve agent antidote kit containing atropine and pralidoxime chloride; delivered as a single dose through one needle.

duplex The ability to transmit and receive simultaneously.

dura mater The outermost layer of the three meninges that enclose the brain and spinal cord; the toughest meningeal layer.

durable power of attorney for health care A type of advance directive executed by a competent adult that appoints another individual to make medical treatment decisions on the person's behalf in the event that the person making the appointment has a loss of decision-making capacity; also see *health care proxy*.

duration of action The amount of time a medication concentration can be expected to remain above the minimum level needed to provide the intended action.

duty A medicolegal term relating to certain personnel who either by statute or by function have a responsibility to provide patient care.

dysarthria The inability to pronounce speech clearly; often due to loss of the nerves or brain cells that control the small muscles in the larynx.

dysbarism injuries Any signs and symptoms caused by the difference between the surrounding atmospheric pressure and the total gas pressure in various tissues, fluids, and cavities of the body.

dysconjugate gaze Paralysis of gaze or lack of coordination between the movements of the two eyes.

dysmenorrhea Painful menstruation.

dysphagia Pain, discomfort, or difficulty in swallowing.

dysplasia An alteration in the size, shape, and organization of cells.

dyspnea Shortness of breath or difficulty breathing.

dysrhythmia An irregular or abnormal heart rhythm.

early adult A young adult age 19 to 40 years.

ecchymosis Bruising or discoloration associated with bleeding within or under the skin.

echolalia Meaningless echoing of the interviewer's words by the patient.

eclampsia Convulsions (seizures) resulting from severe hypertension in the pregnant woman.

ectopic pregnancy A pregnancy in which the ovum implants somewhere other than the uterine endometrium.

edema The presence of abnormally large amounts of fluid between cells in body tissues, causing swelling of the affected area.

effacement Thinning and shortening of the cervix; a normal process that occurs as the uterus contracts.

ejection fraction The portion of the blood ejected from the ventricle during systole.

elder abuse Any action or inaction on the part of a family member, caregiver, or other associated person that takes advantage of the older adult's person, property, or emotional state; also called parent battering.

elective abortion Intentional expulsion of the fetus.

electrical energy Energy delivered in the form of high voltage.

electrolytes Charged atoms or compounds that result from the loss or gain of an electron. These are ions that the body uses to perform certain critical metabolic processes.

emancipated minor A person who is under the legal age in a given state (age 18 years in most cases) but, because of other circumstances, is legally considered an adult.

embolus A blood clot or other substance in the circulatory system that breaks free from its site of origin and obstructs blood flow in a distant blood vessel.

embryo The term used to describe the developing infant from fertilization to the end of the eighth week of gestation.

embryonic period The period of gestation between weeks 3 and 8 in which all major organ systems begin to develop.

emergency A serious situation, such as injury or illness, that threatens the life or welfare of a person or group of people and requires immediate intervention.

emergency doctrine The principle of law that permits a health care provider to treat a patient in an emergency situation when the patient is incapable of granting consent because the person is unresponsive, delusional, exhibiting an altered mental status as a result of drug or alcohol use, or is otherwise physically unable to give expressed consent; also see *implied consent*.

emergency medical care Immediate care or treatment.

emergency medical dispatch (EMD) A system that assists dispatchers in selecting appropriate units to respond to a particular call for assistance and provides callers with vital instructions until the arrival of emergency medical services crews.

emergency medical dispatcher (EMD) A specially trained member of the emergency medical services team who receives information, makes decisions about resource allocation, and relays that information in an organized manner during the emergency.

emergency medical responder (EMR) The first trained person, such as a police officer, firefighter, lifeguard, or other rescuer, to arrive at the scene of an emergency to provide initial medical assistance.

emergency medical services (EMS) A multidisciplinary system that represents the combined efforts of several professionals and agencies to provide prehospital emergency care to sick and injured people.

emergency medical technician (EMT) An individual trained in basic emergency medical care skills, including automated external defibrillation, use

of a definitive airway adjunct, and assisting patients with certain medications.

Emergency Medical Treatment and Active Labor Act (EMTALA) A federal law enacted to combat the practice of patient dumping and that pays particular attention to the practice of sending women in labor to distant hospitals; prevents emergency department staff from denying medical screening or stabilizing treatment, or inappropriately transferring a patient whose condition is not stable to another hospital.

emergency move A move in which the patient is dragged or pulled from a dangerous scene before a primary survey and care are provided.

Emergency Response Guidebook (ERG) A preliminary action guide for first responders operating at a hazardous materials incident in coordination with the US Department of Transportation's (DOT) labels and placards marking system. Jointly developed by the DOT, the Secretariat of Communications and Transportation of Mexico, and Transport Canada.

emesis Vomiting.

emotional intelligence The ability to understand and manage your own emotions and properly respond to others' emotions.

emphysema A disease of the lungs in which there is extreme dilation and eventual destruction of pulmonary alveoli with poor exchange of oxygen and carbon dioxide; it is one form of chronic obstructive pulmonary disease.

encoded A message that has been put into a code before it is transmitted.

endocardium The thin membrane lining the inside of the heart.

endocrine glands Glands that secrete or release chemicals that are used inside the body.

endocrine system The complex message and control system that integrates many body functions, including the release of hormones.

endometriosis A condition in which endometrial tissue grows outside the uterus.

endometritis An inflammation of the endometrium that often is associated with a bacterial infection.

endometrium The innermost layer of the uterine wall.

- end-organ perfusion** The status of perfusion to the vital organs of the body; determined by assessing capillary refill time.
- endosteum** A layer that lines the inner surfaces of bone.
- endotracheal (ET) intubation** Insertion of an endotracheal tube directly through the larynx between the vocal cords and into the trachea to maintain and protect an airway.
- end-stage renal disease (ESRD)** A condition in which the kidneys have lost all ability to function, and toxic waste materials build up in the patient's blood; occurs after acute or chronic kidney disease.
- end-tidal carbon dioxide (ETCO₂)** The partial pressure or maximal concentration of carbon dioxide at the end of an exhaled breath.
- end-tidal carbon dioxide (ETCO₂) monitor** A detection device for monitoring the amount of carbon dioxide in exhaled air that can be used to adjust oxygen administration or ventilations.
- enhanced 9-1-1** An emergency communications system that collects information about 9-1-1 calls from the telephone network, such as the telephone number and location of the caller, and displays this information on the dispatcher's computer terminal.
- enteral** Drugs that are administered along any portion of the gastrointestinal tract, including the oral and rectal routes.
- enteral medications** Medications that are given through a portion of the gastrointestinal tract.
- entrance wound** The point at which a penetrating object enters the body.
- entrapment** To be caught (trapped) within a vehicle, room, or other confined space with no way out, or to have a limb or other body part trapped.
- envenomation** The act of injecting venom.
- environmental emergency** A medical condition caused or exacerbated by the weather, terrain, or by atmospheric pressure at high altitude or underwater.
- enzymes** Substances designed to speed up the rate of specific biochemical reactions.
- eosinophils** Leukocytes that may play a role following infection in various areas in the body.
- epicardium** The layer of the serous pericardium that lies closely against the heart; also called the visceral pericardium.
- epidemic** An outbreak of a disease in which new cases in a human population substantially exceed the number expected based on recent experience.
- epidermis** The outer layer of skin, which is made up of cells that are sealed together to form a watertight protective covering for the body.
- epididymitis** An infection that causes inflammation of the epididymis along the posterior border of the testis; a possible complication of male urinary tract infection.
- epidural hematoma** An accumulation of blood between the skull and the dura mater.
- epiglottis** A thin, leaf-shaped valve that allows air to pass into the trachea but prevents food and liquid from entering.
- epiglottitis** An acute bacterial infection that results in rapid swelling of the epiglottis and surrounding tissues; may cause upper airway obstruction; also referred to as acute supraglottic laryngitis.
- epinephrine** A substance produced by the body (commonly called adrenaline), and a drug produced by pharmaceutical companies that increases pulse rate and blood pressure; the drug of choice for treating an anaphylactic reaction.
- epiphyseal plate** The growth plate of the bone; responsible for normal bone growth and development during childhood.
- epiphyses** The articular end of a long bone; also called the epiphyseal plates.
- epistaxis** Nosebleed.
- eponym** The name of a disease, device, procedure, or drug that is based on the person who invented, discovered, or first described it.
- erythropoiesis** The process by which red blood cells are made.
- eschar** The thick, coagulated crust or slough of leathery skin that develops following a burn.
- esophageal intubation** Improper placement of an advanced airway device into the esophagus rather than into the trachea.
- esophageal varices** Enlarged veins in the lower esophagus caused by obstruction of the portal

vessels leading to increased pressure in esophageal veins and ultimately causing the capillary network of the esophagus to leak.

esophagitis Inflammation of the lining of the esophagus.

esophagus A collapsible tube that extends from the pharynx to the stomach; contractions of the muscle in the wall of the esophagus propel food and liquids through it to the stomach.

estrogen A hormone released from the ovaries that stimulates the uterine lining during the menstrual cycle.

ethics The philosophy of right and wrong, of moral duties, and of ideal professional behavior.

ethnocentrism A person's attitude that the person's own cultural values are more important than those of people from different cultures.

evaporation Conversion of water or another fluid from a liquid to a gas.

evidence-based medicine (EBM) An approach to medicine where decisions are based on well-conducted research, methods that have proven effective in improving patient outcomes, and individual patient characteristics and values; recommendations are classified based on the strength of the scientific evidence; also called science-based medicine.

evisceration The displacement of organs outside of the body.

excitability A property of cardiac cells that provides the cells with the ability to respond to electrical impulses.

excretion The elimination of waste products from the body.

exhalation The part of the breathing process in which the diaphragm and the intercostal muscles relax, forcing air out of the lungs.

exit wound The point at which a penetrating object leaves the body, which may or may not be in a straight line from the entry wound.

exocrine glands Glands that excrete chemicals for elimination.

exophthalmos Bulging of the eyes.

expiration The process of moving air out of the lungs.

expiratory reserve volume The amount of air that can be exhaled following a normal exhalation.

exposure A situation in which a person has had contact with blood, body fluids, tissues, or airborne particles in a manner that suggests disease transmission may occur.

expressed consent A type of consent in which a patient gives verbal or nonverbal authorization for provision of emergency medical care or transport.

exsanguination Severe, possibly life-threatening loss of blood.

extension The straightening of a joint.

external jugular IV lines Intravenous catheters established in the jugular veins of the neck.

external respiration The exchange of gases between the lungs and the blood cells in the pulmonary capillaries; also called pulmonary respiration.

external rotation Rotating an extremity at its joint away from the midline.

extracellular fluid (ECF) Fluid outside of the cell, in which most of the body's supply of sodium is contained.

extrapyramidal symptoms A wide array of symptoms such as involuntary movements, tremors, rigidity, muscle contractions, restlessness, and changes in breathing and heart rate, usually as a result of taking antipsychotic drugs.

extremity lift A lifting technique that is used for patients who are supine or in a sitting position on the ground with no suspected extremity or spinal injuries.

extrication Removal of a patient from entrapment or a dangerous situation or position, such as removal from a wrecked vehicle, industrial incident, or building collapse.

extrication supervisor In incident command, the person appointed to determine the type of equipment and resources needed for a situation involving extrication or special rescue; also called the rescue supervisor.

EZ-10 A handheld, battery-powered driver to which a special intraosseous needle is attached; used for insertion of the intraosseous needle into the proximal tibia of children and adults.

- facilitated diffusion** A process whereby a carrier molecule moves substances in or out of cells from areas of higher to lower concentration.
- fallopian tubes** The two hollow tubes or ducts that extend from the uterus to the region of the ovary and serve as a passage for the egg and sperm.
- false imprisonment** The confinement of a person without legal authority or the person's consent that lasts for an appreciable period.
- fascia** The fiberlike connective tissue that covers arteries, veins, tendons, and ligaments.
- fasciitis** Inflammation of the fascia.
- FAST devices** Manual sternal intraosseous devices used in patients age 12 years and older; include an infusion tube, subcutaneous portal, an introducer, a target/strain relief patch, and a protective dome.
- febrile seizures** Seizures that result from sudden high fever, particularly in children.
- Federal Communications Commission (FCC)** The federal agency that has jurisdiction over interstate and international telephone and telegraph services and satellite communications, all of which may involve EMS activity.
- femoral arteries** The principal arteries of the thigh; continuation of the external iliac arteries. These supply blood to the lower abdominal wall, external genitalia, and legs; can be palpated in the groin area.
- femoral head** The proximal end of the femur, articulating with the acetabulum to form the hip joint.
- femoral vein** A continuation of the saphenous vein that drains into the external iliac vein.
- femur** The thighbone; the longest and one of the strongest bones in the body.
- fetal alcohol syndrome (FAS)** A condition caused by the consumption of alcohol by a pregnant woman; characterized by growth and physical problems, mental retardation, and a variety of congenital abnormalities in her child.
- fetal transition** Process through which the fluid in the fetal lungs is replaced with air, the ductus arteriosus constricts, and the neonate begins adequate oxygenation of its own blood.
- fetoscope** A device used for listening to fetal heart tones.
- fetus** The developing, unborn infant inside the uterus; the embryo becomes the fetus at the beginning of the ninth week of gestation.
- fibrin** A white, filamentous protein formed by the action of thrombin on fibrinogen; the protein that polymerizes (bonds) to form the fibrous component of a blood clot.
- fibrinolysis cascade** The breakdown of fibrin in blood clots and the prevention of the polymerization of fibrin into new clots.
- fibrinolytic agent** Medication that dissolves blood clots after they have already formed; promotes the digestion of fibrin.
- fibrinolytic therapy** The use of medications that act to dissolve blood clots.
- fibula** The long bone on the posterior surface of the lower leg.
- Fick principle** A principle stating that the movement and use of oxygen in the body is dependent on adequate concentration of inspired oxygen (F_{iO_2} [fraction of inspired oxygen]), appropriate movement of oxygen across the alveolar-capillary membrane into the arterial bloodstream, adequate number of red blood cells to carry the oxygen, proper tissue perfusion, and efficient off-loading of oxygen at the tissue level.
- filtration** A type of diffusion in which water carries dissolved compounds across the cell membrane; commonly used by the kidneys to clean blood.
- finance and administration** In incident command, the section responsible for accounting of all expenditures.
- first-responder vehicles** Specialized vehicles used to transport emergency medical services equipment and personnel to the scenes of medical emergencies.
- flail chest** A condition in which two or more ribs are fractured in two or more places or in association with a fracture of the sternum, so a segment of chest wall is effectively detached from the rest of the thoracic cage.
- flame burn** A thermal burn caused by flames touching the skin.

flank The region below the rib cage and above the hip.

flash burns Electrothermal injuries caused by arcing of electric current.

flash chamber The area of a catheter that fills with blood to help indicate when a vein is cannulated.

flat affect The absence of emotion; appearing to feel no emotion at all.

flexible stretcher A stretcher that is a rigid carrying device when secured around a patient but can be folded or rolled when not in use.

flexion The bending of a joint.

flexion injuries A type of injury that results from forward movement of the upper body, typically as the result of rapid deceleration, such as in a motor vehicle crash, or with a direct blow to the occiput.

flexion-rotation injuries A type of injury in which both rotation and flexion occur; typically resulting from high acceleration forces; can result in a stable unilateral facet dislocation in the cervical spine.

flight of ideas Accelerated thinking in which the mind skips very rapidly from one thought to the next.

fluid balance The process of maintaining homeostasis through equal intake and output of fluids.

focal brain injury A specific, grossly observable brain injury.

focal pain Pain that is easily identified as being specific to a single location of the body.

focal seizures Seizures that start in one area of the brain; classified as either aware or impaired-awareness, and further as motor or nonmotor (absence).

focused assessment A type of physical assessment typically performed on patients who have sustained nonsignificant mechanisms of injury or on responsive medical patients. This type of exam is based on the chief complaint and focuses on one body system or part.

follicle-stimulating hormone A hormone released from the pituitary gland at roughly monthly intervals that helps to stimulate one oocyte to undergo cell division.

fontanelles Areas where the neonate's or infant's skull bones have not fused together; usually disappear at approximately 18 months of age.

foodborne transmission The contamination of food or water with an organism that can cause disease.

footprint The area of contact between the tire and the surface of the road.

foramen magnum A large opening at the base of the skull through which the brain connects to the spinal cord.

foramen ovale An opening between the two atria that is present in the fetus but usually closes shortly after birth.

foramina Small openings, perforations, or orifices in the bones of the cranial vault.

forcible restraint The act of physically subduing a patient to prevent harm.

fossa ovalis A depression between the right and left atria that indicates where the foramen ovale had been located in the fetus.

four-person log roll The recommended procedure for moving a patient with a suspected spinal injury from the ground to a long backboard.

Fowler position A sitting position, with the head elevated at a 90° angle (sitting straight upright).

fracture A break in the continuity of a bone.

free radical A molecule that is missing one electron in its outer shell.

free-flow oxygen Oxygen administered via oxygen tube and a cupped hand on the patient's face.

freelancing When individual units or different organizations make independent and often inefficient decisions about the next appropriate action.

freight bills The shipping papers used for transport of chemicals along roads and highways; also referred to as bills of lading.

frequency The number of cycles (oscillations) per second of a radio signal.

friction The resistance to the motion of one body against another.

frontal lobe The portion of the brain that is important in voluntary motor actions and personality traits.

- frostbite** Damage to tissues as the result of exposure to cold; frozen body parts.
- frostnip** A condition in which tissues have been exposed to dangerously cold elements but are still pliable; no permanent tissue damage occurs unless it escalates to frostbite; deeper tissues are unaffected.
- full-body exam** A systematic head-to-toe exam that is performed during the secondary assessment of a patient who has sustained a significant mechanism of injury, is unresponsive, or is in critical condition.
- full-thickness burns** The burns that affect all skin layers and may affect the subcutaneous layers, muscle, bone, and internal organs, leaving the area dry, leathery, and white, dark brown, or charred (eschar); formerly called a third-degree burn.
- functional disorder** A disorder in which there is no known physiologic reason for the abnormal functioning of an organ or organ system.
- functional residual capacity** The volume of air remaining in the lungs following exhalation; also referred to as oxygen reserve.
- fundus** The uppermost part of the uterus, farthest from the cervical opening.
- G agents** Early nerve agents that were developed by German scientists in the period after World War I and into World War II sarin, soman, and tabun.
- gag reflex** A normal reflex mechanism that causes retching; activated by touching the soft palate or the back of the throat.
- gallbladder** A sac on the undersurface of the liver that collects bile from the liver and discharges it into the duodenum through the common bile duct.
- gamma (x-ray) radiation** A type of energy that is emitted from a strong radiologic source that is far faster and has more energy than alpha and beta radiation. These rays easily penetrate through the human body and require lead or several inches of concrete to prevent penetration.
- gamma-hydroxybutyrate (GHB)** A sedative and central nervous system depressant.
- gangrene** An infection commonly caused by *Clostridium perfringens*. The result is tissue destruction and gas production that may result in death.
- gastric distention** A condition in which air fills the stomach, often as a result of high volume and pressure during artificial ventilation.
- gastritis** Inflammation of the stomach.
- gastroenteritis** A family of conditions resulting in diarrhea, nausea, and vomiting; some have infectious causes.
- gastroesophageal reflux disease (GERD)** A condition in which the sphincter between the esophagus and the stomach opens, allowing stomach acid to move superiorly; can cause a burning sensation within the chest (heartburn); also called acid reflux disease.
- gauge** In the medication administration sense, the interior diameter of a catheter or needle.
- gel** A semiliquid substance that is administered orally through capsules or plastic tubes.
- general adaptation syndrome** The body's response to stress that begins with an alarm response, followed by a stage of reaction and resistance, and then recovery or, if the stress is prolonged, exhaustion.
- general impression** The overall initial impression that determines the priority for patient care; based on the patient's surroundings, the mechanism of injury, nature of illness, signs and symptoms, and the chief complaint.
- generalized anxiety disorder (GAD)** A disorder in which a person worries about everything for no particular reason, or the worrying is unproductive and the person cannot decide what to do about an upcoming situation.
- generalized seizures** Seizures that result from abnormal electrical discharges from large areas of the brain, involving both hemispheres.
- generalized tonic-clonic seizures** Seizures characterized by severe twitching of all of the body's muscles that may last several minutes or more; formerly known as a grand mal seizure.
- generic name** The original chemical name of a medication (in contrast with one of its trade names); not capitalized.
- genital herpes** An infection of the genitals, buttocks, or anal area caused by herpes simplex

virus, which may cause sores of the genitals, mouth, or lips.

genital system The reproductive system in males and females.

geriatrics The assessment and treatment of disease in someone 65 years or older.

germinal layer The deepest layer of the epidermis where new skin cells are formed.

gestation The process of fetal development following fertilization of an egg.

gestational diabetes Diabetes that develops during pregnancy in women who did not have diabetes before pregnancy.

gestational diabetes mellitus The condition in which progesterone (the pregnancy hormone) makes the cells resistant to insulin, resulting in the potential for hypoglycemia or hyperglycemia; typically resolves following delivery.

gestational hypertension High blood pressure that develops after the 20th week of pregnancy in women with previously normal blood pressures, and that resolves spontaneously in the postpartum period; formerly known as pregnancy-induced hypertension.

gestational period The time that it takes for a fetus to develop in utero; normally takes 38 weeks.

glands Cells or organs that selectively remove, concentrate, or alter materials in the blood and then secrete them back into the body.

Glasgow Coma Scale (GCS) A method of evaluating the level of consciousness that uses a scoring system for neurologic responses to specific stimuli.

glaucoma A disease of the eye caused by an increase in intraocular pressure; when severe enough, this may damage the optic nerve and potentially cause permanent loss of vision.

glenoid fossa The part of the scapula that forms the socket in the ball-and-socket joint of the shoulder.

globe The eyeball.

glottic opening The narrowest portion of the adult's airway; space between the vocal cords.

glucagon The hormone released from the alpha cells in the islets of Langerhans that converts

glycogen to glucose when the body's blood glucose level drops.

gluconeogenesis A process that stimulates both the liver and the kidneys to produce glucose from noncarbohydrate molecules.

glucose One of the basic sugars; it is the primary fuel, along with oxygen, for cellular metabolism.

glycogen A long polymer from which glucose is converted in the liver (animal starch).

glycogenolysis The process by which glycogen is broken down and converted to glucose; facilitated by glucagon.

glycolysis The conversion of glucose into energy via metabolic pathways.

Golden Hour The time from injury to definitive care, during which treatment of shock and traumatic injuries should occur because survival potential is best; sometimes called the Golden Period.

gonads The reproductive glands.

gonorrhea A sexually transmitted infection caused by *Neisseria gonorrhoeae*.

Good Samaritan laws Statutory provisions enacted by many states to protect citizens from liability for errors and omissions in giving good faith emergency medical care, unless there is wanton, gross, or willful negligence.

governmental immunity Legal doctrine that can protect an emergency medical services provider from being sued or that may limit the amount of the monetary judgment that the plaintiff may recover; generally applies only to emergency medical services systems that are operated by municipalities or other government entities.

grand multipara A term used to describe a woman who has delivered five or more viable infants.

granulocytes Leukocytes that have large cytoplasmic granules that are easily seen with a simple light microscope.

gravid Pregnant.

gravida A term used to describe the number of times a woman has been pregnant.

greater trochanter A bony prominence on the proximal lateral side of the thigh, just below the hip joint.

- greenstick fracture** An incomplete fracture of a bone; seen in children, whose bones are pliable and may not completely fracture.
- gross negligence** Conduct that constitutes a willful or reckless disregard for a duty or standard of care.
- growth plates** Structures located on either end of an infant's long bone, which aid in lengthening bones as the child grows; also known as epiphyseal plates.
- grunting** An "uh" sound heard during exhalation; reflects the child's attempt to keep the alveoli open; a sign of increased work of breathing.
- gtt** A measurement that indicates drops.
- guarding** Involuntary muscle contractions (spasm) of the abdominal wall to minimize the pain of abdominal movement and protect the inflamed abdomen; a sign of peritonitis.
- Guillain-Barré syndrome** A disease of unknown cause characterized by progressive paralysis moving from the feet to the head (ascending paralysis); if paralysis reaches the diaphragm, the patient may require respiratory support.
- gum elastic bougie** A flexible device that is inserted between the glottis under direct laryngoscopy; the endotracheal tube is threaded over the device, facilitating its entry into the trachea.
- habituation** The situation in which there is a physical tolerance and psychological dependence on a drug or drugs.
- half-life** The time required by the body, tissue, or organ to metabolize or inactivate one-half of the amount of a substance taken in; an important consideration in determining the proper dose of drug and frequency of administration.
- hallucinations** Sense perceptions not founded on objective reality; false perceptions.
- hallucinogen** An agent that produces false perceptions in any one of the five senses.
- hangman's fracture** The most classic distraction injury, which occurs when a person is hanged by the neck. The result is a bilateral fracture of C2 with an associated traumatic subluxation of C2 on C3.
- haptan** A substance that normally does not stimulate an immune response but can be combined with an antigen and at a later point initiate an antibody response.
- hazardous materials** Any substances that are toxic, poisonous, radioactive, flammable, or explosive and cause injury or death with exposure.
- hazardous materials (hazmat) incident** An incident in which a hazardous material is no longer properly contained and isolated.
- head injury** A traumatic insult to the head that may result in injury to soft tissue of the scalp and bony structures of the head and skull, not including the face.
- head tilt–chin lift maneuver** A combination of two movements to open the airway by tilting the forehead back and lifting the chin; not used for trauma patients.
- head trauma** A general term that includes both head injuries and traumatic brain injuries.
- health care directive** A written document that specifies medical treatment for a competent patient, should the person become unable to make decisions; also see *advance directive*.
- health care proxy** A type of advance directive executed by a competent adult that appoints another individual to make medical treatment decisions on the person's behalf in the event that the person making the appointment loses decision-making capacity; also see *durable power of attorney for health care*.
- health information exchange** A system that allows EMS providers to access relevant health data (eg, past medical problems, medications, allergies, end-of-life decisions), avoid unnecessary duplication of effort in data entry, and view patient outcomes related to hospital care.
- Health Insurance Portability and Accountability Act (HIPAA)** The law enacted in 1996 that provides for criminal sanctions as well as for civil penalties for releasing a patient's protected health information in a way not authorized by the patient.
- heart** A hollow muscular organ that pumps blood throughout the body.
- heart failure** A disorder in which the heart loses part of its ability to effectively pump blood, usually as a result of damage to the heart muscle and usually resulting in a backup of fluid into the lungs.

heat cramps Painful muscle spasms usually associated with vigorous activity in a hot environment.

heat exhaustion A form of heat injury in which the body loses substantial amounts of fluid and electrolytes because of heavy sweating; also called heat prostration or heat collapse.

heatstroke A life-threatening condition of severe hyperthermia caused by exposure to excessive natural or artificial heat, marked by warm, dry skin; severely altered mental status; and often irreversible coma.

helper T cell A type of T lymphocyte that is involved in cell-mediated and antibody-mediated immune responses. It secretes cytokines that stimulate the B cells and other T cells.

hematemesis Vomit with blood; can either look like coffee grounds, indicating the presence of partially digested blood, or contain bright-red blood, indicating active bleeding.

hematochezia The passage of stool in which bright-red blood can be distinguished; caused by lower gastrointestinal bleeding.

hematologic disorder Any disorder of the blood.

hematology The study and prevention of blood-related disorders.

hematoma An accumulation of blood in the tissues or in a body cavity.

hematopoiesis The process of generating blood cells.

hematopoietic system The system that includes all blood components and the organs involved in their development and production.

hematuria The presence of blood in the urine.

hemiparesis Weakness on one side of the body.

hemiplegia Paralysis of one side of the body, possibly from a stroke or head injury.

hemochromatosis An inherited disease in which the body absorbs more iron than it needs and stores it in the liver, kidneys, and pancreas.

hemoglobin An iron-containing protein within red blood cells that has the ability to combine with oxygen; carries 97% of oxygen.

hemolytic anemia A disease characterized by increased destruction of the red blood cells. It can occur from an Rh factor reaction (primarily

in Rh-positive neonates born to sensitized Rh-negative mothers), exposure to chemicals, or a disorder of the immune system.

hemolytic crisis A rapid destruction of red blood cells that occurs faster than the body's ability to create new cells.

hemolytic disorders Disorders relating to the breakdown of red blood cells.

hemoperitoneum Collection of blood in the abdominal cavity.

hemophilia A congenital abnormality in which the body is unable to produce clots due to a lack of normal clotting factors, resulting in uncontrollable bleeding.

hemopneumothorax A collection of blood and air in the pleural cavity.

hemoptysis The spitting or coughing up of blood.

hemorrhage A discharge of blood from the blood vessels; bleeding.

hemorrhagic shock A condition in which low blood volume due to massive internal or external bleeding results in inadequate perfusion.

hemorrhagic stroke One of the two main types of stroke; occurs as a result of bleeding inside the brain.

hemostasis Formation of clots to plug openings in injured blood vessels and stop blood flow; the body's natural blood-clotting mechanism.

hemostatic agent Pharmacologic substances used to stop profuse bleeding and that function by absorbing the water component of blood, thereby concentrating the clotting factors, activating platelets, and enhancing the coagulation cascade.

hemostatic disorders Bleeding and clotting abnormalities.

hemothorax A collection of blood in the pleural cavity.

heparin A substance found in large amounts in basophils that inhibits blood clotting.

hepatic portal system A specialized part of the venous system that drains blood from the stomach, intestines, and spleen.

hepatic veins The veins into which blood empties after liver cells in the sinusoids of the liver

extract nutrients, filter the blood, and metabolize various drugs.

hepatitis Inflammation of the liver, usually caused by a viral infection, that causes fever, loss of appetite, jaundice, fatigue, and altered liver function.

Hering-Breuer reflex The protective nervous system mechanism that terminates inhalation and prevents lung overexpansion.

hernia The protrusion of a loop of an organ or tissue through an abnormal body opening.

herniation A process in which tissue is forced out of its normal position, such as when the brain is forced from the cranial vault, either through the foramen magnum or over the tentorium.

herpes simplex A common virus caused by human herpes viruses 1 and 2, characterized by small blisters whose location depends on the type of virus. Type 2 results in blisters on the genital area, while type 1 results in blisters on nongenital areas.

high-level disinfection The killing of pathogenic agents by using potent means of disinfection.

hilum The point of entry for the bronchi, vessels, and nerves into each lung.

hinge joints Joints that can bend and straighten but cannot rotate; they restrict motion to one plane.

histamine Chemical substance released by the immune system in allergic reactions that is responsible for many of the symptoms of anaphylaxis, such as vasodilation; increases vascular permeability and tissue inflammation; found in large amounts in basophils.

history taking A step within the patient assessment process that provides detail about the patient's chief complaint and an account of the patient's signs and symptoms.

hollow organs Structures through which materials pass, such as the stomach, gallbladder, small intestine, large intestine, ureters, and urinary bladder.

homeostasis A tendency to constancy or stability in the body's internal environment; the balance of all systems of the body.

homonyms Words that sound alike but are spelled differently and have different meanings.

horizontal axis The axis that runs perpendicular to the sagittal plane; also called the mediolateral axis.

hormones Substances formed in specialized organs or glands and carried to another organ or group of cells in the same organism; these regulate many body functions, including metabolism, growth, and body temperature.

hospice An organization that provides end-of-life care to patients with terminal illnesses and their families.

host The organism or person that is attacked by the infecting agent.

hot zone The area immediately surrounding a hazardous materials spill or incident site that endangers life and health. All personnel working in this zone must wear appropriate protective clothing and equipment. Entry requires approval by the incident commander or other designated officer.

human chorionic gonadotropin (hCG) A hormone that stimulates the corpus luteum to produce progesterone during the first 8 weeks of gestation.

human immunodeficiency virus (HIV) The virus that causes infection and ultimately causes acquired immunodeficiency syndrome (AIDS), which damages the cells in the body's immune system so that the body is unable to fight infection or certain cancers.

human papillomavirus (HPV) The most common sexually transmitted infection, caused by a virus, which may cause no symptoms or cause multiple growths in the genital areas.

humerus The supporting bone of the upper arm.

humoral immunity A type of immunity in which B cell lymphocytes produce antibodies called immunoglobulins, which recognize a specific antigen and then react with it.

hydrocarbons Compounds made up of hydrogen and carbon atoms; they are frequently obtained from the distillation of petroleum.

hydroplaning A condition in which the tires of a vehicle may be lifted off the road surface as water builds up under them, making the vehicle feel as though it is floating.

hydrostatic pressure The pressure of water against the walls of its container.

hymen A fold of mucous membrane that partially covers the entrance to the vagina.

Hymenoptera A family of insects that includes bees, wasps, ants, and yellow jackets.

hyoid bone A bone at the base of the tongue that supports the tongue and its muscles.

hyperbaric chamber A chamber, usually a small room, pressurized to a level higher than atmospheric pressure.

hypercalcemia An elevated blood calcium level.

hypercapnia Increased carbon dioxide level in the bloodstream.

hypercholesterolemia An elevated blood cholesterol level.

hyperemesis gravidarum A condition of persistent nausea and vomiting during pregnancy.

hyperesthesia An excessive increase in the sensitivity of an area, particularly in the skin.

hyperextension Extension beyond the normal range of motion.

hyperflexion Flexion beyond the normal range of motion.

hyperglycemia Abnormally high glucose level in the blood.

hyperglycemic crisis Unresponsiveness caused by dehydration, a very high blood glucose level, and ketoacidosis.

hyperkalemia An elevated serum potassium level.

hypermagnesemia An increased serum magnesium level.

hypernatremia A serum sodium level greater than or equal to 143 mEq/L.

hyperosmolar hyperglycemic nonketotic syndrome (HHNS) A metabolic derangement that occurs principally in patients with type 2 diabetes; it is characterized by hyperglycemia, hyperosmolarity, and an absence of significant ketosis.

hyperoxia An excess of oxygen.

hyperphosphatemia An elevated serum phosphate level.

hyperplasia An increase in the actual number of cells in an organ or tissue, usually resulting in an increase in the size of the organ or tissue.

hyperpyrexia A high body temperature.

hypersensitivity Abnormal sensitivity; a condition in which the body manifests an exaggerated response to the stimulus of a foreign agent.

hypertension Blood pressure that is higher than the normal range.

hypertensive emergency An emergency situation created by excessively high blood pressure, which can lead to serious complications such as stroke or aneurysm.

hyperthermia A condition in which the body core temperature rises to 101°F (38.3°C) or higher.

hypertonic Concentration of solute is higher compared with another solution.

hypertonic solution A solution that has a greater concentration of sodium than does the cell; the increased extracellular osmotic pressure can draw water out of the cell and cause it to collapse.

hypertrophy An increase in the size of the cells as a result of synthesis of more subcellular components, resulting in an increase in tissue and organ size.

hyperventilation Rapid or deep breathing that lowers the blood carbon dioxide level below normal; may lead to increased intrathoracic pressure, decreased venous return, and hypotension when associated with bag-mask device use.

hyperventilation syndrome (panic attack) A syndrome that occurs in the absence of other physical problems and whose symptoms include anxiety, dizziness, numbness, tingling of the hands and feet, and dyspnea despite rapid breathing.

hyphema Bleeding into the anterior chamber of the eye; results from direct ocular trauma.

hypocalcemia A decreased serum calcium level.

hypoglycemia Abnormally low glucose level in the blood.

hypoglycemic crisis Unresponsiveness or altered mental status in a patient with diabetes caused by significant hypoglycemia; usually the result of excessive exercise or activity, failure to eat after a routine dose of insulin, or an inadvertent overdose of insulin.

hypokalemia A decreased serum potassium level.

- hypomagnesemia** A decreased serum magnesium level.
- hyponatremia** A serum sodium level that is less than or equal to 135 mEq/L.
- hypoperfusion** A condition that occurs when the level of tissue perfusion decreases below that needed to maintain normal cellular functions.
- hypophosphatemia** A decreased serum phosphate level.
- hypotension** Blood pressure that is lower than the normal range.
- hypothalamic-pituitary-adrenal axis** A major part of the neuroendocrine system that controls reactions to stress. It is the mechanism for a set of interactions among glands, hormones, and parts of the midbrain that mediate the general adaptation syndrome.
- hypothalamus** The basal part of the diencephalon; it regulates the function of the pituitary gland.
- hypothermia** A condition in which the internal body temperature falls below 95°F (35°C), usually as a result of prolonged exposure to cool or freezing temperatures.
- hypotonic** A lower concentration of sodium in a solution than exists in the cell; the increased intracellular osmotic pressure lets water flow into the cell, causing it to swell and possibly burst.
- hypotonic solution** A solution that has a lower concentration of sodium than the cell does; the increased intracellular osmotic pressure lets water flow into the cell, causing it to swell and possibly burst.
- hypoventilation** The movement of inadequate volumes of air into the lungs.
- hypovolemic shock** A condition in which low blood volume, due to massive internal or external bleeding or extensive loss of body water, results in inadequate perfusion.
- hypoxemia** A deficiency of oxygen in arterial blood.
- hypoxia** A dangerous condition in which the body's tissues and cells do not have enough oxygen.
- hypoxic drive** A backup system that controls respirations by sensing when the oxygen level in the blood falls.
- iatrogenic response** An adverse condition induced in a patient by the treatment given.
- idiopathic** Of no known cause.
- idiosyncrasy** An abnormal sensitivity or reaction to a drug or other substance that is peculiar to an individual.
- idiosyncratic reaction** A peculiar or individual response to a drug or medication through unusual susceptibility.
- i-gel** A supraglottic airway device that uses a non-inflatable, gel-like mask to isolate the larynx and facilitate ventilation.
- ileostomy** The procedure to create an opening (stoma) between the ileum (part of the small intestine) and the surface of the body to provide drainage of the bowel.
- ileus** Paralysis of the bowel, arising from any one of several causes; it stops the contractions that normally move material through the intestine.
- ilium** One of three bones that fuse to form the pelvic ring.
- illicit** In relation to drugs, illegal drugs such as marijuana, cocaine, and lysergic acid diethylamide.
- immersion foot** A condition that occurs after prolonged exposure to cold water, in which the skin of the foot is pale and cold, and there is a loss of sensation; also called trench foot.
- imminent abortion** A spontaneous abortion that cannot be prevented.
- immune** Resistant to disease.
- immune response** The body's defense reaction to any substance that is recognized as foreign.
- immune system** The body system that includes all of the structures and processes designed to mount a defense against foreign substances and disease-causing agents.
- immunity** In medicine, the body's ability to protect itself from acquiring a disease; in a legal context, legal protection from penalties that could normally be incurred under the law.
- immunodeficiency** An abnormal condition in which some part of the body's immune system is inadequate, and, consequently, resistance to infectious disease is decreased.

immunogen An antigen that is capable of generating an immune response.

immunoglobulins Antibodies secreted by the B cells.

immunosuppressant medications The medications intended to inhibit the body's ability to attack the "foreign" transplanted organ or in the case of autoimmune diseases, the medications that inhibit the body's attack on itself.

impedance threshold device (ITD) A valve device placed between the endotracheal tube and a bag-mask device that limits the amount of air entering the lungs during the recoil phase between chest compressions.

implied consent A type of consent in which a patient who is unable to give consent (because the person is unresponsive, delusional, exhibiting an altered mental status as a result of drug or alcohol use, or is otherwise physically unable to give expressed consent) is given treatment under the legal assumption that the person would want treatment; also see *emergency doctrine*.

inappropriate affect Emotion that is out of synch with the situation (for example, wearing a waxy smile while discussing a parent's death).

incidence The number of new cases of a disease in a population.

incident action plan An oral or written plan stating general objectives reflecting the overall strategy for managing an incident.

incident commander (IC) The overall leader of the incident command system to whom commanders or leaders of incident command system divisions report.

incident command system (ICS) An on-scene emergency management model specifically designed to provide for an integrated organizational structure that reflects the complexity and demands of an incident, including disasters and mass-casualty incidents. Also called the incident management system.

incomplete abortion Expulsion of the fetus that results in some products of conception remaining in the uterus.

incontinence Loss of bowel and bladder control; can be due to a generalized tonic-clonic seizure and to other conditions.

incubation period The time between when a person is exposed to an agent to when symptoms first appear.

index of suspicion Awareness that unseen serious and/or life-threatening injuries may exist when determining the mechanism of injury.

indications Therapeutic uses for a specific medication.

indirect contact Exposure to or transmission of infection from one person to another by contact with a contaminated object.

indirect injury An injury that occurs when force is applied to one region of the body but causes an injury in another area.

infancy The first year of life.

infant A young child age 1 month to 1 year.

infarcted cells Cells that die as a result of loss of blood flow.

infection The abnormal invasion of a host or host tissues by organisms such as bacteria, viruses, or parasites, with or without signs or symptoms of disease.

infection control Procedures to reduce transmission of infection among patients and health care personnel.

infectious disease A medical condition that is caused by the growth and spread of small, harmful organisms within the body.

inferior Below what is indicated; closer to the feet.

inferior vena cava One of the two largest veins in the body; carries blood from the lower extremities and the pelvic and the abdominal organs to the heart.

infiltration The escape of fluid into the surrounding tissue.

inflammatory response A reaction by tissues of the body to irritation or injury, characterized by pain, swelling, redness, and heat.

influenza A virus that has crossed the animal/human barrier and infected humans and that kills thousands of people every year.

influenza type A (flu) A virus that has crossed the animal/human barrier and has infected humans, recently reaching a pandemic level with the H1N1 strain.

- informed consent** Permission for treatment given by a competent patient after the potential risks, benefits, and alternatives to treatment have been explained.
- ingestion** Eating or drinking materials for absorption through the gastrointestinal tract.
- inhalation** The active, muscular part of breathing that draws air into the airway and lungs; a medication delivery route; in allergic reactions, breathing in foreign substances through the respiratory system.
- inhalation injury** An injury to the airway as a result of breathing smoke and toxic chemicals into the lungs and airway.
- injection** In allergic reactions, piercing of the skin, followed by deposition of foreign material into the skin.
- in loco parentis** Latin phrase meaning “in the place of the parent” that refers to the legal responsibility of a person or organization to take on some of the functions and responsibilities of a parent or legal guardian on the behalf of a minor.
- inotropic** Affecting the contractility of muscle tissue, especially cardiac muscle.
- inotropic effect** Affecting the contractility of muscle tissue, especially cardiac muscle.
- inotropic state** Related to the strength of the heart’s contraction.
- inspiration** The process of moving air into the lungs.
- inspiratory reserve volume** The amount of air that can be inhaled after a normal inhalation; the amount of air that can be inhaled in addition to the normal tidal volume.
- inspiratory/expiratory (I/E) ratio** An expression for comparing the length of inspiration with that of expiration, normally 1:2, meaning that expiration is twice as long as inspiration (not measured in seconds).
- insulin** A hormone produced by the islets of Langerhans (an exocrine gland in the pancreas) that enables sugar in the blood to enter the cells of the body; used in synthetic form to treat and control diabetes mellitus.
- integumentary system** The largest organ system in the body, consisting of the skin and accessory structures (eg, hair, nails, glands).
- intended effect** The effect that a medication is expected to have on the body.
- interatrial septum** A membrane that separates the right and left atria.
- interference** A direct biochemical interaction between two drugs.
- interferon** A protein produced by cells in response to viral invasion that is released into the bloodstream or intercellular fluid to induce healthy cells to manufacture an enzyme that counters the infection.
- interleukins** Chemical substances that attract white blood cells to the sites of injury and bacterial invasions.
- intermodal tanks** Shipping and storage vessels that can be either pressurized or nonpressurized.
- internal respiration** The exchange of gases between the blood cells and the tissues.
- internal rotation** Rotating the anterior surface of an extremity toward the midline.
- internal shunt** Also called an arteriovenous fistula, this device is an artificial connection between a vein and an artery, usually in the forearm or upper arm.
- international terrorism** Terrorism that is carried out by people associated with, or inspired by, a defined terrorist organization or nation; also known as cross-border terrorism.
- interoperable communications system** A communications system that uses a voice-over-Internet-protocol (VoIP) technology to allow multiple agencies to communicate and transmit data.
- interrogatories** Written questions that the defense and plaintiff send to one other.
- interstitial** Water between the vascular system and the surrounding cells (for example, between the membranes of two cells located outside the vascular compartment in the body).
- interstitial fluid** The fluid located outside of the blood vessels in the spaces between the body’s cells.
- interstitial space** The space in between the cells.
- interventricular septum** A thick wall that separates the right and left ventricles.

intervertebral disks The cushions that lie between the vertebrae.

intracellular fluid (ICF) Fluid within cells in which most of the body's supply of potassium is contained.

intracerebral hematoma Bleeding within the brain tissue (parenchyma) itself; also referred to as an intraparenchymal hematoma.

intracranial pressure (ICP) The pressure within the cranial vault.

intramuscular (IM) Injection into a muscle; a medication delivery route.

intranasal (IN) A delivery route in which a medication is pushed through a specialized atomizer device, called a mucosal atomizer device, into the naris.

intraosseous (IO) Injection into the bone; a medication delivery route.

intraosseous space The spongy cancellous bone of the epiphyses and the medullary cavity of the diaphysis, collectively.

intrapulmonary shunting Bypassing of oxygen-poor blood past nonfunctional alveoli to the left side of the heart.

intravascular The water portion of the circulatory system surrounding the blood cells (for example, in the heart, arteries, or veins).

intravascular fluid (plasma) The noncellular portion of blood found within the blood vessels; also called plasma.

intravenous (IV) Injection into a vein; a medication delivery route.

involuntary activities Actions of the body that are not under a person's conscious control.

involuntary muscle A muscle over which a person has no conscious control. It is found in many automatic regulating systems of the body.

ionic concentration The amount of charged particles found in a particular area.

ionizing radiation Energy that is emitted in the form of rays or particles.

ions Charged atoms or compounds that result from the loss or gain of an electron.

ipsilateral On the same side of the body.

iris The muscle and surrounding tissue behind the cornea that dilate and constrict the pupil, regulating the amount of light that enters the eye; pigment in this tissue gives the eye its color.

irreversible shock The final stage of shock, resulting in death.

irritable bowel syndrome (IBS) A condition in which patients have abdominal pain and changes in their bowel habits; generally, the pain must be present for at least 3 days per month for at least 3 months to be considered this disease.

ischemia A lack of oxygen that deprives tissues of necessary nutrients, resulting from partial or complete blockage of blood flow; potentially reversible because permanent injury has not yet occurred.

ischemic cells Cells that receive enough blood after an event, such as a cerebrovascular accident, to stay alive but not enough to function properly.

ischemic stroke One of the two main types of stroke; occurs when blood flow to a particular part of the brain is cut off by a blockage (for example, a clot) inside a blood vessel.

ischium One of three bones that fuse to form the pelvic ring.

islets of Langerhans Structures found in the pancreas that are composed of four types of cells; one type, the beta cell, is responsible for the production of insulin.

isoimmunity The formation of antibodies or T cells that are directed against antigens or another person's cells.

isolette A device used to transport a neonate in an ambulance; also called an incubator.

isotonic The same concentration of sodium in a solution as in the cell. In this case, water does not shift, and no change in cell shape occurs.

isotonic solution A solution that has the same concentration of solutes as does the cell. In this case, water does not shift, and no change in cell shape occurs.

Jamshidi needle A double needle, consisting of a solid-bore needle inside a sharpened hollow needle; used to access the medullary canal for intraosseous infusion.

- jaundice** Yellow skin or sclera commonly caused by liver disease or dysfunction.
- jaw-thrust maneuver** Technique to open the airway by placing the fingers behind the angle of the jaw and bringing the jaw forward; used for patients who may have a cervical spine injury.
- joint** The point at which two or more bones articulate, or come together.
- joint (articulation)** The point at which two or more bones articulate, or come into contact.
- joint capsule** The fibrous sac that encloses a joint.
- joint information center (JIC)** An area designated by the incident commander, or a designee, in which public information officers from multiple agencies distribute information about the incident.
- jugular veins** The two main veins that drain the head and neck.
- jugular venous distention (JVD)** A prominence of the jugular veins caused by increased volume or increased pressure within the central venous system or the thoracic cavity.
- jump kit** A portable kit containing items that are used in the initial care of the patient.
- JumpSTART triage** A sorting system for pediatric patients younger than 8 years or weighing less than 100 pounds (45 kg); the system is modified for infants because they cannot ambulate on their own.
- junctional tourniquet** A bleeding control method used when a traditional tourniquet is not appropriate (inguinal or axillary hemorrhage); can also be used as a pelvic immobilization device.
- Kehr sign** Left shoulder pain caused by blood in the peritoneal cavity due to rupture of the spleen.
- ketoacidosis** An acidotic state created by the production of ketones via fat metabolism.
- ketonemia** Excess amounts of ketone bodies in the blood.
- ketones** Acidic by-products of fat metabolism.
- kidnapping** The seizing, confining, abducting, or carrying away of a person by force, including transporting a competent adult for medical treatment without the person's consent.
- kidney stones** Solid crystalline masses formed in the kidney, resulting from an excess of insoluble salts or uric acid crystallizing in the urine; these masses may become trapped anywhere along the urinary tract.
- kidneys** Two retroperitoneal organs that excrete the end products of metabolism as urine and regulate the body's salt and water content.
- killer T cells** The cells released during a type IV allergic reaction that kill antigen-bearing target cells.
- kinetic energy** The energy of a moving object.
- kinetics** The study of the relationship among speed, mass, vector direction, and physical injury.
- King LT airway** A single-lumen airway that is blindly inserted into the esophagus; when properly placed in the esophagus, one cuff seals the esophagus, and the other seals the oropharynx.
- kinin system** A group of polypeptides that mediate inflammatory responses by stimulating visceral smooth muscle and relaxing vascular smooth muscle to produce vasodilation.
- Kussmaul respirations** Deep, rapid breathing; the result of an accumulation of certain acids when insulin is not available in the body.
- kyphosis** A condition in which the back becomes hunched over due to an abnormal curvature of the spine.
- labia majora** Two prominent, rounded folds of skin lateral to the labia minora of the female external genitalia.
- labia minora** A pair of skin folds in the female external genitalia that border the vestibule.
- labored breathing** Breathing that requires greater than normal effort; may be slower or faster than normal and characterized by grunting, stridor, and use of accessory muscles; occurs when air movement is impaired.
- laceration** A smooth or jagged open wound.
- lacrimal glands** The glands that produce fluids to keep the eye moist; also called tear glands.
- lactated Ringer solution** A sterile crystalloid isotonic intravenous solution of specified amounts of calcium chloride, potassium chloride, sodium chloride, and sodium lactate in water.

lactic acid A metabolic end product of the breakdown of glucose that accumulates when metabolism proceeds in the absence of oxygen.

lactic acidosis Anaerobic cellular respiration due to hypoperfusion of tissues and organs.

landline Communications system linked by wires, usually in reference to a conventional telephone system.

large intestine The portion of the digestive tube that encircles the abdomen around the small bowel, consisting of the cecum, the colon, and the rectum. It helps regulate water balance and eliminate solid waste.

laryngeal mask airway (LMA) An airway device that is inserted into the mouth blindly and comes to rest at the glottic opening. A flexible cuff is inflated, creating an almost airtight seal.

laryngectomy A surgical procedure in which the larynx is removed.

laryngospasm The spasmodic contraction of the vocal cords, accompanied by an enfolding of the arytenoid and aryepiglottic folds.

larynx A complex structure formed by the epiglottis, thyroid cartilage, cricoid cartilage, arytenoid cartilage, corniculate cartilage, and cuneiform cartilage; the voice box.

lateral In anatomy, parts of the body that lie farther from the midline.

lateral compression A force that is directed from the side toward the midline of the body.

lateral malleolus An enlargement of the distal end of the fibula, which forms the lateral wall of the ankle joint.

LD₅₀ The standard measure of the dose amount of an agent or substance that will kill 50% of a population who are exposed to this level.

Le Fort fractures Maxillary fractures that are classified into three categories based on their anatomic location.

left anterior descending (LAD) artery One of the two branches of the left main coronary artery, which is the largest and shortest of the myocardial blood vessels; this and the circumflex coronary artery supply blood to the left ventricle and other areas.

length-based resuscitation tape A tape used to estimate an infant or child's weight on the basis of length; appropriate drug doses and equipment sizes are listed on the tape; one type is called a Broselow tape.

lens The transparent part of the eye through which images are focused on the retina.

leukocytosis An elevated white blood cell count, often due to inflammation; other causes include parasitic infections, bone tumors, and leukemia.

leukopenia A reduction in the number of white blood cells.

leukotrienes Arachidonic acid metabolites that function as chemical mediators of inflammation; released by the immune system in allergic reactions; also known as slow-reacting substances of anaphylaxis.

Level A protection Personal protective equipment used for protection against vapors, gases, mists, and even dusts. The highest level of protection, it is an encapsulating suit that includes a self-contained breathing apparatus.

Level B protection Personal protective equipment used when the type and atmospheric concentration of substances require a high level of respiratory protection but less skin protection. The kinds of gloves and boots worn depend on the identified chemical.

Level C protection Personal protective equipment used when the type of airborne substance is known, the concentration is measured, the criteria for using an air-purifying respirator are met, and skin and eye exposure is unlikely. This ensemble consists of standard work clothing with the addition of chemical-protective clothing, chemically resistant gloves, and a form of respiratory protection.

Level D protection Personal protective equipment used when the atmosphere contains no known hazard, and work functions preclude splashes, immersion, or the potential for unexpected inhalation of or contact with hazardous levels of chemicals. This is the lowest level of protection and is primarily a work uniform that includes coveralls.

lewisite (L) A vesicant that has a rapid onset of symptoms and produces immediate, intense

pain and discomfort on contact; British antilewisite is the antidote.

liaison officer In incident command, the person who relays information and concerns among command, the general staff, and other agencies.

libel False and damaging information about a person that is communicated in writing.

licensure The process whereby a competent authority, usually the state, allows people to perform a regulated job, trade, or profession.

licit In relation to drugs, legalized drugs such as coffee, alcohol, and tobacco.

life expectancy The average number of years a person can be expected to live.

ligament A band of fibrous tissue that connects bones to bones; supports and strengthens a joint.

lightening Movement of the fetus down into the pelvis prior to birth.

limb presentation A delivery in which the presenting part is a single arm, leg, or foot.

limbic system Structures within the cerebrum and diencephalon that influence emotions, motivation, mood, and sensations of pain and pleasure.

linear skull fractures Types of skull fracture that commonly occur in the temporal-parietal region of the skull; not associated with deformities to the skull; also referred to as nondisplaced skull fractures.

lipolysis The metabolism (breakdown or destruction) of stored fat that has been released into the circulation.

lithium The cornerstone drug for the treatment of bipolar disorder.

liver A large solid organ that lies in the right upper quadrant immediately below the diaphragm; it produces bile, stores glucose for immediate use by the body, and produces many substances that help regulate immune responses.

load-distributing band (LDB) A circumferential chest compression device composed of a constricting band and backboard that is either electrically or pneumatically driven to compress the heart by putting inward pressure on the thorax.

local reaction A mild or moderate allergic reaction that the body limits to a specific area after being exposed to a foreign substance.

logistics In incident command, the section that procures and stockpiles equipment and supplies during an incident.

lone wolf terrorist attack An act of terror carried out by a single person to further an ideological goal.

longitudinal axis The axis that runs perpendicular to the transverse plane.

longitudinal section The view of an object cut along its long axis.

loosening of associations A situation in which the logical connection between one idea and the next becomes obscure, at least to the listener.

lumbar spine The lower part of the back, formed by the lowest five nonfused vertebrae; also called the dorsal spine.

lumen The inside diameter of an artery or other hollow structure.

lung compliance The ability of the alveoli to fully expand when air is drawn in during inhalation.

lungs The two primary organs of breathing.

lutinizing hormone A hormone released from the pituitary gland at roughly monthly intervals that helps to stimulate one oocyte to undergo cell division.

lymph A thin, plasmalike liquid formed from interstitial or extracellular fluid that bathes the tissues of the body.

lymph nodes Round or bean-shaped structures interspersed along the course of the lymph vessels, where infection fighting cells are housed, and which filter the lymph and serve as a source of lymphocytes.

lymph vessels Thin-walled vessels through which lymph circulates through the body; they travel close to the major veins.

lymphatic system A passive circulatory system in the body that transports a plasmalike liquid called lymph, a thin fluid that bathes the tissues of the body.

lymphocytes The smallest of the agranulocytes; they originate in the bone marrow but migrate through the blood to the lymphatic tissues.

lymphokines Cytokines released by lymphocytes, including many of the interleukins, gamma interferon, tumor necrosis factor beta, and chemokines.

lysis The process of disintegration, breakdown, or rupturing of cells caused by either the presence of certain enzymes, or from excess water entering the cell through osmosis.

macrodrrip set An administration set named for the large orifice between the piercing spike and the drip chamber; allows for rapid fluid flow into the vascular system.

macrophages Cells that are responsible for protecting the body against infection.

macular degeneration Deterioration of the central portion of the retina.

main stem bronchi The part of the lower airway below the larynx through which air enters the lungs.

malfeasance An unauthorized act committed outside the scope of medical practice as defined by law.

Mallory-Weiss tear A tear in the mucous membrane, or inner lining, where the esophagus and the stomach meet, causing severe bleeding and potentially death.

malocclusion Misalignment of the teeth.

mammary glands The organs of milk production in the breasts.

mandible The bone of the lower jaw.

mania A mental disorder characterized by abnormally exaggerated happiness, joy, or euphoria with hyperactivity, insomnia, and grandiose ideas.

manually triggered ventilation (MTV) device A fixed flow rate ventilation device that delivers a breath every time its button is pushed; also referred to as a flow-restricted, oxygen-powered ventilation device.

manubrium The upper fourth of the sternum.

margination The loss of fluid from the blood vessels into the tissue, causing the blood left in the vessels to have increased viscosity, which in turn slows the flow of blood and produces stasis.

marijuana The dried leaves and flower buds of the *Cannabis sativa* plant, which are smoked to achieve a high.

mass-casualty incidents (MCIs) Emergency situations that can place great demand on the equipment or personnel of the EMS system or have the potential to overwhelm available resources.

massive hemothorax An accumulation of more than 1,500 mL of blood within the pleural space.

mast cells Cells located in the tissues that release chemical mediators in response to an antigen-antibody reaction.

mastoid process A prominent bony mass at the base of the skull behind the ear.

maxillae The upper jawbones that assist in the formation of the orbit, the nasal cavity, and the palate and hold the upper teeth.

mean arterial pressure (MAP) The average pressure against the arterial wall during a cardiac cycle; generally considered to be the same as blood pressure.

mechanical energy The energy that results from motion (kinetic energy) or that is stored in an object (potential energy).

mechanical piston device A device that depresses the sternum via a compressed gas-powered or electric-powered plunger mounted on a backboard.

mechanism of action The way in which a medication produces the intended response.

mechanism of injury (MOI) The forces, or energy transmission, applied to the body that cause injury; the way in which traumatic injuries occur.

meconium The newborn's first bowel movement.

meconium staining The occurrence of a dark-green material in the amniotic fluid that can cause lung disease in the newborn.

MED channels Very high-frequency and ultrahigh-frequency channels that the Federal Communications Commission has designated exclusively for EMS use.

medevac Medical evacuation of a patient by helicopter.

medial In anatomy, parts of the body that lie closer to the midline.

medial malleolus The distal end of the tibia, which forms the medial side of the ankle joint.

- mediastinitis** Inflammation of the mediastinum that often results when gastric contents leak into the thoracic cavity after esophageal perforation.
- mediastinum** The space between the lungs, in the center of the chest, that contains the heart, trachea, large blood vessels, main stem bronchi, part of the esophagus, lymphatic channels, and paired vagus and phrenic nerves.
- medical ambiguity** Uncertainty regarding the specific cause of the patient's condition.
- medical control** Physician instructions given directly by radio or cell phone (online/direct) or indirectly by protocol/guidelines (off-line or indirect), as authorized by the medical director of the service program.
- medical director** The physician who authorizes or delegates to the provider the authority to perform health care in the field.
- medical emergencies** Emergencies caused by illnesses or conditions, not by an outside force.
- medical incident command** In incident command, the position responsible for the triage, treatment, and transport of injured people; also known as the medical or emergency medical services branch of the incident command system.
- medical necessity** A standard used by Medicare to determine whether a patient's condition requires ambulance transport in a particular situation.
- medication** A chemical substance that is used to treat or prevent disease or relieve pain.
- medication interactions** Situations in which the effects of one medication alter the response of another medication.
- medicolegal** A term relating to medical jurisprudence (law) or forensic medicine.
- medulla** A part of the brainstem that continues inferiorly with the spinal cord; serves as a conduction pathway for ascending and descending nerve tracts; coordinates heart rate, blood vessel diameter, breathing, swallowing, vomiting, coughing, and sneezing.
- medulla oblongata** Nerve tissue that is continuous inferiorly with the spinal cord; serves as a conduction pathway for ascending and descending nerve tracts; coordinates heart rate, blood vessel diameter, breathing, swallowing, vomiting, coughing, and sneezing.
- medullary canal** The space within the bone that contains bone marrow.
- medullary cavity** An internal cavity that contains bone marrow.
- meiosis** A type of cell division that occurs in the production of eggs and sperm.
- melena** Dark, tarry, malodorous stools caused by upper gastrointestinal bleeding.
- membrane attack complex** Molecules that insert themselves into the bacterial membrane, leading to weakened areas in the membrane.
- menarche** The initial onset of menstruation occurring during puberty; the first menstrual cycle.
- meninges** A set of three tough membranes, the dura mater, arachnoid, and pia mater, that enclose and protect the entire brain and spinal cord within the skull and the spinal canal.
- meningitis** An inflammation of the meningeal coverings of the brain and spinal cord; it is usually caused by a virus or a bacterium.
- meningococcal meningitis** An inflammation of the meningeal coverings of the brain and spinal cord; can be highly contagious.
- menopause** The cessation of the menstrual cycle and ovarian function.
- menstrual cycle** A cycle lasting approximately 28 days in which physiologic changes occur in the uterus and associated reproductive organs.
- menstruation** The period in the menstrual cycle of sloughing and discharge of the functional layer of the endometrium; occurs approximately every 28 days.
- mental disorder** An illness with psychological or behavioral symptoms and/or impairment in functioning, caused by a social, psychological, genetic, physical, chemical, or biologic disturbance; may also be referred to as a psychiatric disorder.
- mental model** The overall picture that team members have in their head of what needs to happen to ensure an effective response.
- metabolic** Relating to the breakdown of ingested foodstuffs into smaller and smaller molecules

and atoms that are used as energy sources for cellular function.

metabolic acidosis A pathologic condition characterized by a blood pH of less than 7.35 and caused by accumulation of acids in the body from a metabolic cause.

metabolic alkalosis A pathologic condition characterized by a blood pH of greater than 7.45 and caused by an accumulation of bases in the body from a metabolic cause.

metabolism The chemical processes that provide the cells with energy from nutrients.

metacarpal bones The bones that form the hand.

metaplasia A reversible, cellular adaptation in which one adult cell type is replaced by another adult cell type.

metered-dose inhaler (MDI) A miniature spray canister used to direct medications through the mouth to be inhaled into the lungs.

methamphetamine A highly addictive drug in the amphetamine family.

methicillin-resistant *Staphylococcus aureus* (MRSA) A bacterium that can cause infections in different parts of the body and is often resistant to commonly used antibiotics; it is transmitted by different routes, including the respiratory route, and can be found on the skin, in surgical wounds, and in the bloodstream, lungs, and urinary tract.

metric system A decimal system based on 10s for the measurement of length, weight, and volume.

microangiopathy Microscopic deterioration of vessel walls caused primarily by adherence of blood lipids to vessel walls.

microdrip set An administration set named for the small orifice between the piercing spike and the drip chamber; allows for carefully controlled fluid flow and is ideally suited for medication administration.

midbrain The part of the brain that is responsible for helping to regulate the level of consciousness.

middle adult An adult age 41 to 60 years.

midsagittal plane (midline) An imaginary vertical line drawn from the middle of the forehead through the nose and the umbilicus (navel) to the floor.

mild airway obstruction A condition in which an obstruction leaves the patient able to exchange some air, but also causes some degree of respiratory distress.

minute volume The amount of air moved in and out of the respiratory tract (minus the dead space) per minute; determined by the tidal volume multiplied by the respiratory rate. Also called minute ventilation.

miosis Excessively constricted (pinpoint) pupil; often bilateral after exposure to nerve agents.

misfeasance Appropriate act performed in an improper manner, such as a medication administered at the wrong dose.

mission-critical communications Any communications in which disruption will result in the failure of the task at hand.

mitosis The division of the nucleus of a cell.

mitral valve The valve in the heart that separates the left atrium from the left ventricle.

mobile data terminal (MDT) A small computer terminal inside an ambulance that directly receives data from the dispatch center.

Mobile Integrated Healthcare (MIH) A system of delivering health care services within the community, rather than at a physician's office or a hospital, with an integrated team of health care professionals.

mobile radio A radio that is mounted inside a vehicle and used to communicate with dispatch or medical control; it operates at lower power than a base station (20 to 50 watts) and is assigned to a specific radio frequency band.

monoamine oxidase inhibitors (MAOIs) Psychiatric medication used primarily to treat atypical depression by increasing norepinephrine and serotonin levels in the central nervous system.

monocytes Agranulocytes that migrate out of the blood and into the tissues in response to an infection.

mons pubis The pad of fatty tissue and coarse skin that lies over the pubic symphysis.

mood disorders Disorders in which the disturbance of mood is accompanied by full or partial manic or depressive syndrome.

- morality** A code of conduct that can be defined by society, religion, or a person, affecting character, conduct, and conscience.
- morbid obesity** An excessively unhealthy accumulation of body fat, defined as a body mass index of greater than or equal to 40 kg/m².
- morbidity** Number of nonfatally injured or disabled people; usually expressed as a rate, meaning the number of nonfatal injuries in a certain population in a given time period divided by the size of the population.
- morgue supervisor** In incident command, the person who works with area medical examiners, coroners, and law enforcement agencies to coordinate the disposition of dead patients.
- Moro reflex** An infant reflex in which, when an infant is caught off guard, the infant opens the arms wide, spreads the fingers, and seems to grab at things.
- mortality** The quality of being mortal; number of deaths from a disease in a given population.
- motor nerves** Nerves that carry information from the central nervous system to the muscles of the body.
- mucosal atomizer device** A device that attaches to the end of a syringe that is used to spray (atomize) certain medications via the intranasal route.
- mucous membranes** The lining of body cavities and passages that communicate directly or indirectly with the environment outside the body.
- mucus** The opaque, sticky secretion of the mucous membranes that lubricates the body openings.
- multigravida** A term used to describe a woman who has been pregnant more than once.
- multilumen airway device** A type of airway device with a single long tube that can be used for esophageal obturation or endotracheal tube ventilation, depending on where it comes to rest following blind positioning.
- multipara** A term used to describe a woman who has delivered two or more viable infants.
- multiple organ dysfunction syndrome (MODS)** A progressive condition that occurs after severe illness or injury, usually characterized by combined failure of two or more organs or organ systems not affected by the patient's initial illness or injury, along with some clotting mechanisms.
- multiple sclerosis (MS)** A severe, incurable degenerative disorder involving the central nervous system (brain and spinal cord).
- multiple-casualty incident** Any situation with more than one patient, but which will not overwhelm available resources.
- multiplex** Simultaneous transmission of multiple data streams, most often voice and electrocardiographic signals, in either or both directions over the same frequency.
- multisystem trauma** A term that describes the injuries of a person who has been subjected to multiple traumatic injuries involving more than one body system; these patients have a high level of morbidity and mortality.
- murmur** An abnormal heart sound, heard as a “whooshing” sound, indicating turbulent blood flow within the heart.
- muscarinic cholinergic antagonists** Medications that block acetylcholine exclusively at the muscarinic receptors; an example is atropine.
- muscular dystrophy** A category of incurable genetic diseases that cause a slow, progressive degeneration of the muscle fibers.
- musculoskeletal system** The bones and voluntary muscles of the body.
- mutagen** A substance that mutates, damages, and changes the structures of the body's cells.
- mutism** The absence of speech.
- mutual aid response** An agreement between neighboring emergency medical services systems to respond to mass-casualty incidents or disasters in each other's region when local resources are insufficient to handle the response.
- myelin** An insulating layer, or sheath, made up of fatty substances and protein that form around the nerves.
- myocardial contractility** The ability of the heart muscle to contract.
- myocardial contusion** A bruise of the heart muscle.
- myocardial infarction** Blockage of the arteries that supply oxygen to the heart, resulting in death to a portion of the myocardium.

myocardial rupture An acute perforation of the ventricles, atria, intraventricular septum, intra-atrial septum, chordae, papillary muscles, or valves.

myocardium The heart muscle.

myoclonus Hyperactive reflexes; occurs during severe preeclampsia.

myoglobin A pigment synthesized in the muscles to give skeletal muscles their red-brown color.

myometrium A thick smooth muscle that forms the middle layer of the uterine wall.

nares The external openings of the nostrils.

nasal cannula An oxygen-delivery device in which oxygen flows through two small, tubelike prongs that fit into the patient's nostrils.

nasal cavity The chamber inside the nose that lies between the floor of the cranium and the roof of the mouth.

nasal flaring Widening of the nostrils, indicating that an airway obstruction is present.

nasal septum The separation between the right and left nostrils.

nasopharyngeal (nasal) airway An airway adjunct inserted into the nostril of a responsive patient who is not able to maintain a natural airway.

nasopharynx The part of the pharynx that lies above the level of the roof of the mouth, or palate.

National EMS Scope of Practice Model A document created by the National Highway Traffic Safety Administration that outlines the skills performed by various emergency medical services providers.

National Incident Management System (NIMS) A Department of Homeland Security system designed to enable federal, state, and local governments, private-sector and nongovernmental organizations, and all other organizations who assume a role in emergency management to effectively and efficiently prepare for, prevent, respond to, and recover from domestic incidents, regardless of cause, size, or complexity, including acts of catastrophic terrorism and hazardous materials incidents.

natural immunity A nonspecific cellular and humoral response that operates as the body's first line of defense against pathogens; this develops

as part of being exposed to an antigen and developing antibodies; also called native immunity.

nature of illness (NOI) The general type of illness a patient is experiencing.

nebulizer A device for producing a fine spray or mist that is used to deliver inhaled medications.

necrosis The death of tissue, usually caused by a cessation of the blood supply.

necrotizing fasciitis Death of tissue from bacterial infection, caused by more than one infecting organism—most commonly, *Staphylococcus aureus* and hemolytic streptococci; this condition has a high mortality rate.

negative-pressure ventilation Drawing of air into the lungs; airflow from a region of higher pressure (outside the body) to a region of lower pressure (the lungs); occurs during normal (unassisted) breathing.

neglect Refusal or failure on the part of the caregiver to provide life necessities, such as needed care, services, or supervision.

negligence Failure to provide the same care that a person with similar training would provide.

negligence per se A theory that may be used when the conduct of the person being sued is alleged to have occurred in clear violation of a statute.

Neisseria meningitidis A form of bacterial meningitis characterized by rapid onset of symptoms, often leading to shock and death.

neologisms Invented words that have meaning only to their inventor.

neonate A newborn age birth to 1 month.

neoplasm A mass of tissue produced by abnormal cell growth and division that may be malignant (cancerous) or benign; a tumor.

nephrons The structural and functional units of the kidney that form urine; composed of the glomerulus, the glomerular (Bowman) capsule, the proximal convoluted tubule, loop of Henle, and the distal convoluted tubule.

nerve agents A class of chemical called organophosphates; they function by blocking an essential enzyme in the nervous system, which causes the body's organs to become overstimulated and burn out.

- nerve root injury** Injury to a nerve at the level of the spinal cord.
- nervous system** The system that controls virtually all activities of the body, both voluntary and involuntary.
- neurogenic shock** Circulatory failure caused by paralysis of the nerves that control the size of the blood vessels, resulting in widespread vasodilation and loss of sympathetic nervous system tone; seen in patients with spinal cord injuries.
- neuronal soma** The body of a neuron (nerve cell).
- neuropathy** A group of conditions in which the nerves leaving the spinal cord are damaged, resulting in distortion of signals to or from the brain.
- neurotic disorders** A collection of mental disorders without psychotic symptoms and lacking the intense psychopathology of other mood disorders; includes anxiety disorders, phobias, and panic disorder.
- neurotoxins** Biologic agents that are the most deadly substances known to humans; they include botulinum toxin and ricin.
- neurotransmitters** The chemicals produced by the body that stimulate electrical reactions in adjacent neurons.
- neurovascular compromise** The loss of the nerve supply, blood supply, or both to a region of the body, typically distal to a site of injury; characterized by alterations in sensation, including numbness and tingling, or by a loss or decrease of motor function; vascular compromise is indicated by weak or absent pulses, poor skin color, and cool skin.
- neutron radiation** The type of energy that is emitted from a strong radiologic source, involving particles that are among the most powerful forms of radiation; the particles easily penetrate through lead and require several feet of concrete to stop them.
- neutrophils** One of the three types of granulocytes; they have multilobed nuclei that resemble a string of baseballs held together by a thin strand of thread; they destroy bacteria, antigen-antibody complexes, and foreign matter.
- New Intraosseous (NIO) device** A spring-loaded device that contains neither drill nor battery, used for inserting an intraosseous needle into the proximal tibia of an adult patient.
- newborn** The phase of life from the first few minutes to the first hours after birth.
- noise** Anything that dampens or obscures the true meaning of a message.
- nonbarbiturate hypnotics** Medications designed to sedate without the side effects of a barbiturate.
- nonbulk storage vessels** Any container other than bulk storage containers such as drums, bags, compressed gas cylinders, and cryogenic containers. These hold commonly used commercial and industrial chemicals such as solvents, industrial cleaners, and compounds.
- nondisplaced fracture** A simple crack in the bone that has not caused the bone to move from its normal anatomic position; also called a hairline fracture.
- nonfeasance** Failure to perform a required or expected act.
- nonhemorrhagic shock** Shock that occurs as a result of fluid loss contained within the body, such as in dehydration, burn injury, crush injury, and anaphylaxis.
- nonopioid analgesics** Medications designed to relieve pain without the side effects of opioids.
- nonbreathing mask** A combination mask and reservoir bag system that is the preferred way to give oxygen in the prehospital setting; delivers up to 90% inspired oxygen.
- nonsteroidal anti-inflammatory drugs (NSAIDs)** Medications with analgesic and fever-reducing properties.
- norepinephrine** A neurotransmitter and drug sometimes used in the treatment of shock; produces vasoconstriction through its alpha-stimulator properties.
- normal saline** 0.9% sodium chloride; an isotonic crystalloid.
- nosocomial** Hospital acquired.
- nuchal cord** An umbilical cord that is wrapped around the newborn's neck.
- nuchal rigidity** A stiff or painful neck; commonly associated with meningitis.

nullipara A term used to describe a woman who has never delivered a viable infant.

obesity A complex condition in which a person has an excessive amount of body fat; the result of an imbalance between calories consumed and calories used; defined as a body mass index of greater than or equal to 30 kg/m².

objective information Information that you observe and that is measurable, such as a patient's blood pressure.

obstructive shock Shock that occurs when there is a block to blood flow in the heart or great vessels, causing an insufficient blood supply to the body's tissues.

occipital lobe The portion of the brain that is responsible for the processing of visual information.

occiput The posterior (back) aspect of the head.

occlusion Blockage, usually of a tubular structure such as a blood vessel.

occlusive dressing A dressing made of gauze with petroleum jelly, aluminum foil, or plastic that prevents air and liquids from entering or exiting a wound.

Occupational Safety and Health Administration (OSHA) The federal regulatory compliance agency that develops, publishes, and enforces guidelines concerning safety in the workplace.

oculomotor nerve The cranial nerve (III) that innervates the muscles that cause motion of the eyeballs and upper eyelid.

off-gassing The release of an agent after exposure, such as from a person's clothes that have been exposed to the agent.

official name Drug name assigned by the *United States Pharmacopeia (USP)*, generally the generic name followed by "USP."

older adult An adult age 61 years or older.

olfactory nerve The cranial nerve (I) for smell.

oliguria A decrease in urine output to the extent that total urine output drops to less than 500 mL per day.

oncotic pressure The pressure of water to move, typically into the capillary, as the result of the presence of plasma proteins.

onset of action The time needed for the concentration of the medication at the target tissue to reach the minimum effective level.

oocytes Female sex cells; the precursors to a mature egg.

oogenesis The maturation process that results in production of an ovum, or egg.

open abdominal injury An injury in which there is a break in the surface of the skin or mucous membrane, exposing deeper tissue to potential contamination.

open book pelvic fracture A life-threatening fracture of the pelvis caused by a force that displaces one or both sides of the pelvis laterally and posteriorly.

open chest injury An injury to the chest in which the chest wall itself is penetrated by some external object such as a knife or bullet.

open-ended questions Questions for which the patient must provide detail to give an answer.

open fracture Any break in a bone in which the overlying skin has been damaged.

open head injury An injury to the head often caused by a penetrating object in which there may be bleeding and exposed brain tissue.

open incident An incident that is not yet contained; there may be patients who have yet to be located and the situation may be ongoing, producing more patients.

open injury An injury in which there is a break in the surface of the skin or the mucous membrane, exposing deeper tissue to potential contamination.

open pneumothorax An accumulation of air or gas in the pleural space, resulting from a defect or penetration into the chest wall that allows air to enter the thoracic cavity.

operations In incident command, the section that carries out the orders of the incident commander to help resolve the incident.

opiate Any of the various alkaloids derived from the opium or poppy plant.

opioid A drug that acts as a central nervous system depressant and produces insensibility or stupor. An opioid can be a natural product derived from

the opium or poppy plant or a synthetic product designed to produce similar effects.

opioid agonist-antagonists Medications designed to relieve pain without the side effects of opioids.

opioid agonists Chemicals that are similar to or derived from the opium plant.

opioid antagonists A classification of medications that reverse the effects of opioid drugs.

OPQRST A mnemonic used in evaluating a patient's pain Onset, Provocation/palliation, Quality, Region/radiation, Severity, and Timing of pain.

opsonization The process by which an antibody coats an antigen to facilitate its recognition by immune cells.

optic nerve Either of the second cranial nerves that enter the eyeball posteriorly, through the optic foramen, which transmit visual information to the brain.

oral By mouth; a medication delivery route.

oral glucose A simple sugar that is readily absorbed by the bloodstream; it is carried on the EMS unit.

orbit The eye socket, made up of the maxilla and zygoma.

orchitis A complication of a male urinary tract infection in which one or both testes become infected, enlarged, and tender, causing pain and swelling in the scrotum.

organic brain syndrome Temporary or permanent dysfunction of the brain, caused by a disturbance in the physical or physiologic functioning of brain tissue.

organophosphates A class of chemicals found in many insecticides used in agriculture and in the home.

orientation The mental status of a patient as measured by memory of person (name), place (current location), time (current year, month, and approximate date), and event (what happened).

oropharyngeal (oral) airway An airway adjunct inserted into the mouth to keep the tongue from blocking the upper airway and to make suctioning the airway easier.

oropharynx A tubular structure that extends vertically from the back of the mouth to the esophagus and trachea.

orthopnea Severe dyspnea experienced when lying down that is relieved by a change in position, such as sitting up or standing.

orthostatic hypotension A drop in systolic blood pressure when moving from a lying or sitting to a standing position.

orthostatic vital signs Vital signs assessed in two different patient positions (for example, in the supine and sitting or standing positions) to determine the degree of hypotension; also known as the tilt test.

osmolarity The ability to influence the movement of water across a semipermeable membrane.

osmosis The movement of a solvent (fluid), such as water, from an area of lower solute concentration to one of higher concentration through a selectively permeable membrane to equalize concentrations of a solute on both sides of the membrane.

osmotic pressure Pressure created against the cell wall by the presence of water.

osteogenesis imperfecta A congenital bone disease that results in fragile bones.

osteomyelitis Inflammation of the bone and muscle caused by infection; a potential complication of intraosseous infusion.

osteoporosis A generalized bone disease, commonly associated with postmenopausal women but occurring in either sex, in which there is a reduction in the amount of bone mass, resulting in increased susceptibility to fractures after minimal trauma.

ovaries Glands that lie on either side of the pelvic cavity in a woman and produce sex hormones and ova (eggs).

overdose Consumption of an excessive quantity of a drug that, when taken or administered, can have toxic or lethal consequences.

over-the-counter (OTC) medications Medications that may be purchased directly by a patient without a prescription.

over-the-needle catheters The prehospital standard for intravenous cannulation, these consist of a hollow tube over a laser-sharpened steel needle; also referred to as an angiocath.

overweight An unhealthy accumulation of body fat, defined as a body mass index of 25 to 29.9 kg/m².

ovulation The release of a mature egg (ovum) into the fallopian tube from the ovary.

ovum A mature egg released by the ovary during ovulation.

oxygen saturation (Spo₂) The measure of the percentage of oxygen molecules that are bound to hemoglobin in arterial blood.

oxygen toxicity A condition of excessive oxygen consumption resulting in cellular and tissue damage.

oxygenation The process of delivering oxygen to the blood by diffusion from the alveoli following inhalation into the lungs.

oxytocin A hormone secreted in the pituitary gland that promotes uterine contractions.

packaging The act of preparing a patient for movement as a unit by means of a backboard or similar stabilization device.

paging The use of a radio signal and a voice or digital message that is transmitted to pagers (“beepers”) or desktop monitor radios.

palmar The position in which the palm of the hand is facing forward when in the anatomic position.

palmar grasp An infant reflex that occurs when something is placed in the infant’s palm; the infant grasps the object.

palpate To examine by touch.

pancreas A flat, solid organ that can also be considered a gland, that lies below the liver and the stomach; it is a major source of digestive enzymes delivered into the duodenum, and produces the hormone insulin; considered both an endocrine gland and an exocrine gland.

pancreatitis Inflammation of the pancreas.

pandemic An outbreak of a disease that occurs on a global scale or over a wide area.

panic disorder A disorder characterized by sudden, usually unexpected, and overwhelming feelings of fear and dread, accompanied by a variety of other symptoms produced by a massive activation of the autonomic nervous system.

paper bag syndrome Rupture of the lungs that occurs as the chest meets with blunt trauma after

taking a deep breath, usually during a motor vehicle crash, similar to the rupture of an air-filled paper bag.

papillary muscles Specialized muscles that attach the ventricles to the cusps of the valves by muscular strands called chordae tendineae cordis.

para A term used to describe the number of times a woman has delivered a viable (live) infant.

paradoxical motion The inward movement of the chest during inhalation and outward movement during exhalation; the opposite of normal chest wall movement during breathing; occurs in a flail chest.

paramedic An individual extensively trained in advanced life support, including endotracheal intubation, emergency pharmacology, cardiac monitoring, and other advanced assessment and treatment skills.

paranasal sinuses The sinuses, or hollowed sections of bone in the front of the head, which are lined with mucous membrane and drain into the nasal cavity.

paraplegia Paralysis of the lower part of the body, possibly from thoracic or lumbar spinal injury or spina bifida.

parasympathetic nervous system A subdivision of the autonomic nervous system, involved in control of involuntary, vegetative functions, mediated largely by the vagus nerve through the chemical acetylcholine; the part of the autonomic nervous system that relaxes the body.

parasympatholytics Drugs that block the actions of the parasympathetic nervous system; also known as anticholinergics.

parasympathomimetics Drugs that produce the same effects as those of the parasympathetic nervous system; also known as cholinergics.

parathyroid glands Four glands that are embedded in the posterior portion of each lobe of the thyroid; they produce and secrete parathyroid hormone.

parathyroid hormone Hormone produced and secreted by the parathyroid glands; it maintains normal levels of calcium in the blood and normal neuromuscular function.

parenchyma The tissue of an organ itself.

- parenteral** Drug administration through any route other than through the gastrointestinal tract; includes intravenous, intraosseous, subcutaneous, intramuscular, sublingual, buccal, transcutaneous, intranasal, and inhalation.
- parenteral medications** Medications that are given through any route other than through the gastrointestinal tract.
- paresthesias** Abnormal sensations such as burning, numbness, or tingling.
- parietal lobe** The portion of the brain that is the site for reception and evaluation of most sensory information, except smell, hearing, and vision.
- parietal pleura** The thin membrane that lines the pleural (chest) cavity.
- partial laryngectomy** Surgical removal of a portion of the larynx.
- partial pressure** The term used to describe the amount of gas in air or dissolved in fluid, such as blood.
- partial pressure of carbon dioxide (Paco₂)** A measurement of the amount of carbon dioxide in the blood.
- partial pressure of oxygen (Pao₂)** A measurement of the amount of oxygen in the blood.
- partial rebreathing mask** A mask that is similar to a nonrebreathing mask except there is no one-way valve between the mask and the reservoir; therefore, patients rebreathe a small amount of their exhaled air.
- partial-thickness burns** The burns affecting the epidermis and some portion of the dermis but not the subcutaneous tissue, characterized by blisters and skin that is white to red, moist, and mottled; formerly called a second-degree burn.
- patella** The kneecap; a specialized bone that lies within the tendon of the quadriceps muscle.
- patent** Open, clear of obstruction.
- pathogen** A microorganism that is capable of causing disease in a susceptible host.
- pathologic fracture** A fracture that occurs in an area of abnormally weakened bone.
- pathophysiology** The study of the physiology of altered functioning in the presence of disease.
- patient autonomy** The right of a patient to make informed choices regarding their health care.
- patient care report (PCR)** The legal document used to record all patient care activities. This report has direct patient care functions as well as administrative and quality control functions. PCRs are also known as prehospital care reports.
- peak** In a pharmacologic context, the point of maximum effect of a drug.
- pedal edema** Swelling of the feet and ankles caused by collection of fluid in the tissues; a possible sign of heart failure.
- pediatric assessment triangle (PAT)** A structured assessment tool that allows you to rapidly form a general impression of the infant or child without touching the child; consists of assessing appearance, work of breathing, and circulation to the skin.
- pelvic binders** Devices used to splint the bony pelvis to reduce hemorrhage from bone ends, venous disruption, and pain.
- pelvic inflammatory disease (PID)** An infection of the female upper organs of reproduction, specifically the uterus, ovaries, and fallopian tubes.
- pelvis** The attachment of the lower extremities to the body, consisting of the sacrum and two pelvic bones.
- penetrating trauma** Injury caused by objects that pierce and penetrate the surface of the body and injure the underlying tissues, such as knives and bullets, and damage internal organs and body cavities.
- penetrating wound** An injury that penetrates the skin, resulting from a sharp, pointed object or a blunt object traveling at sufficient speed, such as a knife or a bullet.
- Penrose drain** A type of surgical drain; can be used as a constricting band.
- perfusion** The circulation of oxygenated blood within an organ or tissue in adequate amounts to meet the cells' current needs.
- pericardial fluid** A serous fluid that fills the space between the visceral pericardium and the parietal pericardium and helps to reduce friction.
- pericardial sac** A thick, fibrous membrane that surrounds the heart; also called the pericardium.

pericardial tamponade The impairment of diastolic filling of the right ventricle due to significant amounts of fluid in the pericardial sac surrounding the heart, leading to a decrease in the cardiac output.

pericardiocentesis The ultimate treatment for cardiac tamponade, which involves inserting a needle attached to a syringe far enough into the chest to penetrate the pericardium to withdraw fluid.

pericardium A thick, fibrous membrane that surrounds the heart; also called the pericardial sac.

perineum The area of skin between the scrotum and the anus in males, and the vagina and the anus in females.

periosteum A double layer of connective tissue that lines the outer surface of the bone.

peripheral nerve injury Injury to a nerve anywhere in the body outside the spinal cord.

peripheral nervous system (PNS) The 31 pairs of spinal nerves and 12 pairs of cranial nerves that link the body's other organs to the central nervous system; these may be sensory, motor, or connecting nerves.

peripheral shock Shock caused by peripheral circulatory abnormalities; includes hypovolemic shock and distributive shock.

peripheral vision Visualization of lateral objects while looking forward.

peristalsis The wavelike contraction of smooth muscle by which the ureters or other tubular organs propel their contents.

peritoneal cavity The abdominal cavity.

peritoneum The membrane lining the abdominal cavity (parietal peritoneum) and covering the abdominal organs (visceral peritoneum).

peritonitis Inflammation of the peritoneum.

perseveration Repeating the same idea over and over again.

persistence Describes how long a chemical agent will stay on a surface before it evaporates.

personal protective equipment (PPE) Equipment that blocks exposure to a pathogen or a hazardous material.

personal protective equipment (PPE) levels Indicate the amount and type of protective equipment that an individual needs to avoid injury during contact with a hazardous material.

pertinent negatives Expected signs or symptoms with negative findings that warrant no care or intervention.

pertussis An airborne bacterial infection that affects primarily children younger than 6 years; patients will be feverish and exhibit a “whoop” sound on inspiration after a coughing attack; highly contagious through droplet infection; also called whooping cough.

petechiae Small, purple, nonblanching spots on the skin.

petechial hemorrhages Pinpoint red dots in the sclera of the eye.

pH The measure of acidity or alkalinity of a solution.

phagocytes The cells that engulf and consume foreign material such as microorganisms and debris.

phalanges The small bones of the digits of the fingers and toes.

pharmacodynamics The study of drugs and their actions on living organisms.

pharmacokinetics The study of the metabolism and action of drugs with a particular emphasis on the time required for absorption, duration of action, distribution in the body, and method of excretion.

pharmacology The study of the properties and effects of medications.

phobias Obsessive, irrational fears of specific things or situations, such as fear of heights, fear of open places, fear of confined spaces, or fear of certain animals.

phosgene A very potent respiratory agent that is a product of combustion; it has a delayed onset of symptoms, usually hours.

phosgene oxime (CX) A vesicant that has a rapid onset of symptoms and produces immediate, intense pain and discomfort on contact.

phospholipid bilayer The cell membrane's double layer, consisting of a hydrophilic outer layer composed of phosphate groups, and a hydrophobic

inner layer made up of lipids, or fatty acids. It is this structure and composition that allows the cell membrane to have selective permeability.

phrenic nerve The nerve that innervates the diaphragm; necessary for adequate breathing.

physical dependence A physiologic state of adaptation to a drug, usually characterized by tolerance to the drug's effects and a withdrawal syndrome if use of the drug is stopped, especially abruptly.

physiology The study of the body functions of the living organism.

physis The growth plate in long bones.

pia mater The innermost and thinnest of the three meninges that enclose the brain and spinal cord; it rests directly on the brain and spinal cord.

piercing spike The hard, sharpened plastic spike on the end of the administration set designed to pierce the sterile membrane of the intravenous bag.

pin-indexing system A system established for portable cylinders to ensure that a regulator is not connected to a cylinder containing the wrong type of gas.

pinna The external, visible part of the ear.

pituitary gland An endocrine gland, located in the sella turcica of the brain, responsible for directly or indirectly affecting all body functions.

placards Signage required to be placed on all four sides of highway transport vehicles, railroad tank cars, and other forms of hazardous materials transportation; the sign identifies the hazardous contents of the vehicle, using a standardization system with 10¾-inch (27-cm) diamond-shaped indicators.

placenta Tissue attached to the uterine wall that nourishes the fetus through the umbilical cord.

placenta previa A condition in which the placenta develops over and partially or completely covers the cervix.

plaintiff In a civil lawsuit, the person who brings a legal action against another person.

planning In incident command, the section that ultimately produces a plan to resolve any incident.

plantar The sole or bottom surface of the foot.

plantar flexion Bending of the foot toward the ground.

plasma A sticky, yellow fluid made mostly of water, but also electrolytes, clotting factors, and glucose, that is a component of blood that carries the blood cells, formed elements, and nutrients and transports cellular waste material to the organs of excretion.

plasmin An enzyme that dissolves the fibrin in blood clots.

platelets Tiny, disk-shaped elements that are much smaller than the cells; they are essential in the initial formation of a blood clot, the mechanism that stops bleeding.

pleura The serous membrane covering the lungs and lining the thoracic cavity, completely enclosing a potential space known as the pleural space.

pleural cavity The potential space between the visceral and parietal pleura.

pleural effusion A collection of fluid between the lung and chest wall that may compress the lung.

pleural friction rub A squeaking or grating sound that occurs when the pleural linings rub together, which may be heard on inspiration, expiration, or both; commonly caused by inflammation of the pleura.

pleural space Potential space between the visceral and parietal pleura of the lung and chest wall, respectively; it is normally absent, as these surfaces are usually in direct contact.

pleuritic chest pain Sharp, stabbing pain in the chest that is worsened by a deep breath or other chest wall movement; often caused by inflammation or irritation of the pleura.

pneumatic antishock garment (PASG) An inflatable device that covers the legs and abdomen; used to splint the lower extremities or pelvis, or to control bleeding in the lower extremities or pelvis.

pneumonia An infectious disease of the lung that damages lung tissue.

pneumonic plague A lung infection, also known as plague pneumonia, that is the result of inhalation of plague-causing bacteria.

pneumonitis Lung inflammation from an irritant, such as a chemical, dust, or radiation, or from aspiration, such as aspiration of gastric contents.

pneumoperitoneum Air in the peritoneal cavity.

pneumotaxic (pontine) center A portion of the pons that assists in creating shorter, faster respirations.

pneumothorax A partial or complete accumulation of air in the pleural space.

point tenderness Tenderness that is sharply localized at the site of the injury, found by gently palpating along the bone with the tip of one finger.

points of distribution (PODs) Existing facilities used as mass distribution sites for antibiotics, chemical antidotes, antitoxins, vaccinations, and other medications and supplies during an emergency.

poison A substance whose chemical action could damage structures or impair function when it is introduced into the body.

polydipsia Excessive thirst persisting for long periods despite reasonable fluid intake; often the result of excessive urination.

polymorphonuclear neutrophils (PMNs) The type of white blood cells formed by bone marrow tissue that have a nucleus consisting of several parts or lobes connected by fine strands.

polyphagia Excessive eating; in diabetes, the inability to use glucose properly can cause a sense of hunger.

polypharmacy The simultaneous use of many medications by the same patient.

polyuria The passage of an unusually large volume of urine in a given period; in diabetes, this can result from wasting of glucose in the urine.

pons An organ that lies below the midbrain and above the medulla and contains numerous important nerve fibers, including those for sleep, respiration, and the medullary respiratory center.

popliteal artery A continuation of the femoral artery at the knee.

portable radio A handheld two-way radio with a limited range and low power (1 to 5 watts).

portable stretcher A stretcher with a strong, rectangular, tubular metal frame and rigid fabric stretched across it.

portal vein The blood vessel that transports blood from the gastrointestinal tract to the liver.

portal venous system Special venous drainage system that takes blood from the intestines to the liver.

positive end-expiratory pressure (PEEP) Mechanical maintenance of pressure in the airway at the end of expiration to increase the volume of gas remaining in the lungs.

postconventional reasoning A type of reasoning in which a child bases decisions on their conscience.

posterior In anatomy, the back surface of the body; the side away from you in the standard anatomic position.

posterior tibial artery The artery just behind the medial malleolus; supplies blood to the foot.

postictal state The period following a seizure that lasts between 5 and 30 minutes, characterized by labored respirations and some degree of altered mental status.

postpartum eclampsia Eclampsia that occurs after a woman has delivered a newborn; can occur up to several weeks after the birth.

posttraumatic stress disorder (PTSD) A delayed stress reaction to a prior incident, characterized by the reliving of the stress and nightmares of the original situation. Often the result of one or more unresolved issues concerning the incident, and may relate to an incident that involved physical harm or the threat of physical harm.

potassium channel blockers Medications that increase the contractility of the heart and work against the reentry of blocked impulses.

potential energy The product of mass (weight), gravity, and height that is converted into kinetic energy and results in injury, such as from a fall.

potentiation Enhancement of the action of a drug by the administration of another drug.

power grip A technique in which the stretcher or backboard is gripped by inserting each hand under the handle with the palm facing up and the thumb extended, fully supporting the underside of the handle on the curved palm with the fingers and thumb.

power lift A lifting technique in which the AEMT's back is held upright, with legs bent, and the patient is lifted when the AEMT straightens the legs to raise the upper body and arms.

- prearrival instructions** Instructions provided by the emergency medical dispatcher to an emergency caller to care for life-threatening emergencies until help arrives.
- precedence** Basing current action on lessons, rules, or guidelines derived from previous similar experiences.
- preconventional reasoning** A type of reasoning in which a child acts almost purely to avoid punishment or to get what the child wants.
- prediabetes** A condition identified in people who have certain risk factors associated with type 2 diabetes and exists when blood glucose levels or hemoglobin A1c levels are above normal levels, yet not high enough to be diagnosed as diabetes.
- pre eclampsia** A condition during pregnancy characterized by hypertension, protein in the urine, and edema; a precursor to eclampsia.
- prefix** The word part that appears before a word root, changing the meaning of the term.
- preload** The precontraction pressure in the heart, which increases as the volume of blood builds up when returned to the heart (venous return); directly affects afterload.
- premature** A newborn that delivers before 36 weeks of gestation or weighs less than 5 lb (2.25 kg) at birth.
- premature rupture of membranes** Rupture of the amniotic sac prior to the onset of labor; increases risk of fetal infection or injury.
- premenstrual syndrome (PMS)** A cluster of all or some of the troubling symptoms that occur during a woman's menstrual phase that can include fluid retention, breast pain and tenderness, headache, severe cramping, and emotional changes, including agitation, irritability, depression, and anger.
- preoxygenation** The process of providing oxygen, often in combination with ventilation, prior to intubation in order to raise the oxygen levels of body tissues; a critical step in advanced airway management. This extends the time during which an advanced airway can be placed in an apneic patient, because the more oxygen that is available in the alveoli, the longer the patient can maintain adequate gas exchange in the lungs during the procedure.
- prepuce** A structure in the female external genitalia that is formed where the labia minora unite over the clitoris.
- presbycusis** An age-related condition of the ear that produces progressive bilateral hearing loss that is most noted at higher frequencies.
- preschool-age** Between 3 and 6 years of age.
- preschooler** A child age 3 to 6 years.
- prescription medications** Medications that are distributed to patients only by pharmacists according to a physician's order.
- pressure infuser device** A sleeve that is placed around the IV bag and inflated to force fluid to flow from the IV bag and into the tubing.
- pressure of speech** Speech in which words seem to tumble out under immense emotional pressure.
- preterm** Before 36 complete weeks of gestation.
- prevalence** The number of cases of a disease in a specific population within a given period.
- priapism** A painful, tender, and persistent erection of the penis; can result from spinal cord injury, use of erectile dysfunction drugs, or sickle cell disease.
- primary apnea** Apnea caused by oxygen deprivation; usually corrected with stimulation, such as drying or slapping the newborn's feet; typically preceded by an initial period of rapid breathing.
- primary blast injury** An injury caused by an explosive pressure wave on the hollow organs of the body.
- primary brain injury** A sudden and profound injury to the brain that is essentially complete at the time of impact; may be caused, for example, by an explosive pressure wave on the hollow organs of the body.
- primary prevention** Efforts to prevent an injury or illness from ever occurring.
- primary response** The first encounter with the foreign substance that initiates the immune response.
- primary service area (PSA)** The designated area in which an emergency medical services agency is responsible for the provision of prehospital emergency care and transportation to the hospital.

primary spinal cord injury Injury to the spinal cord that is a direct result of trauma, for example transection of the spinal cord from penetrating trauma or displacement of ligaments and bone fragments, resulting in compression of the spinal cord.

primary survey A step within the patient assessment process that identifies and initiates treatment of immediate and potential life threats.

primary triage A type of patient sorting used to rapidly categorize patients; the focus is on speed in locating all patients and determining an initial priority as their conditions warrant.

primigravida A woman's first pregnancy.

primipara A woman who has had only one delivery.

progesterone A hormone released from the ovaries that stimulates the uterine lining during the menstrual cycle in preparation for implantation of a fertilized egg.

prolapsed umbilical cord A situation in which the umbilical cord comes out of the vagina before the newborn.

pronation The act of rotating the forearms in a palms-down manner.

prone Lying flat, facedown.

proprioception The ability to perceive the position and movement of one's body or limbs.

prostaglandins A group of lipids that act as chemical messengers.

prostate gland A small gland that surrounds the male urethra where it emerges from the urinary bladder; it secretes a fluid that is part of the ejaculatory fluid.

protected health information (PHI) Any information about health status, provision of health care, or payment for health care that can be linked to an individual. This information is interpreted rather broadly and includes any part of a patient's medical record or payment history.

protocols Precise and detailed plans for a regimen of therapy (for example, advanced cardiac life support algorithms).

proxemics The study of space between people and its effects on communication.

proximal Closer to the trunk.

proximate cause The specific reason that an injury occurred; one of the items that must be proven in order for an advanced emergency medical technician to be held liable for negligence.

pruritus Itching.

psychogenic A symptom or illness that is caused by mental factors as opposed to physical ones.

psychogenic shock Shock caused by a sudden, temporary reduction in blood supply to the brain that causes fainting (syncope).

psychological dependence The emotional state of craving a drug to maintain a feeling of well-being.

psychosis A mental disorder characterized by the loss of contact with reality.

pubic symphysis A hard bony and cartilaginous prominence found at the midline in the lowermost portion of the abdomen where the two halves of the pelvic ring are joined by cartilage at a joint with minimal motion.

pubis One of three bones that fuse to form the pelvic ring.

public health Discipline that is focused on examining the health needs of entire populations with the goal of preventing health problems.

public information officer (PIO) In incident command, the person who keeps the public informed and relays information to the press.

public safety access point A call center staffed by trained personnel who are responsible for managing requests for police, firefighting, and ambulance services.

pulmonary artery The major artery leading from the right ventricle of the heart to the lungs; it carries oxygen-poor blood.

pulmonary blast injuries Pulmonary trauma resulting from short-range exposure to the detonation of high-energy explosives.

pulmonary circulation The flow of blood from the right ventricle through the pulmonary arteries and all of their branches and capillaries in the lungs and back to the left atrium through the venules and pulmonary veins; also called the lesser circulation.

pulmonary contusion A bruise of the lung.

- pulmonary edema** A buildup of fluid in the lungs, usually as a result of left-side heart failure.
- pulmonary embolism** A blood clot that breaks off from a large vein and travels to the blood vessels of the lung, causing obstruction of blood flow.
- pulmonary embolus** A blood clot trapped within the pulmonary circulation.
- pulmonary overpressurization syndrome (POPS)** A diving emergency that can occur during rapid ascent and can cause pneumothorax, mediastinal and subcutaneous emphysema, alveolar hemorrhage, and the lethal air embolism; also called burst lung.
- pulmonary veins** The four veins that return oxygenated blood from the lungs to the left atrium of the heart.
- pulmonary-capillary membrane** The very thin membrane, consisting of only one cell layer, that lies between the alveolus and capillary, through which respiratory exchange between the alveolus and the blood vessels occurs.
- pulmonic valve** The semilunar valve that regulates blood flow between the right ventricle and the pulmonary artery.
- pulse** The wave of pressure created as the heart contracts and forces blood out of the left ventricle and into the major arteries.
- pulse oximetry** An assessment tool that measures oxygen saturation of hemoglobin in the capillary beds.
- pulse pressure** The difference between the systolic blood pressure and the diastolic blood pressure.
- pulsus paradoxus** A drop in the systolic blood pressure of 10 mm Hg or more; commonly seen in patients with cardiac tamponade or severe asthma.
- punitive damages** Compensation that is sometimes awarded in a civil lawsuit when the conduct of the defendant was intentional or constituted a reckless disregard for the safety of the public.
- pupil** The circular opening in the middle of the iris that admits light to the back of the eye.
- purulent** Full of pus; having the character of pus.
- putrefaction** Decomposition of body tissues; a definitive sign of death.
- pyelonephritis** Inflammation of the kidney and renal pelvis.
- pyrogens** Chemicals or proteins that travel to the brain and affect the hypothalamus and stimulate a rise in the body's core temperature.
- quadrants** The four sections of the abdominal cavity shown by two imaginary lines intersecting at the umbilicus, dividing the abdomen into four equal areas.
- quadriplegia** Paralysis of all four extremities and the trunk, possibly from a cervical spine injury.
- quality control** The responsibility of the medical director to ensure the appropriate medical care standards are met by providers on each call.
- quaternary blast injury** A blast injury that falls into one of the following categories: burns, crush injuries, toxic inhalation, medical emergencies, or mental health disorders.
- quinary blast injury** A blast injury caused by exposure to toxic materials associated with radiation, bacteria, and/or chemicals resulting in contamination of tissues, or by foreign bodies that have the potential to transmit disease.
- rabid** Describes an animal that is infected with rabies.
- raccoon eyes** Bruising under the eyes that may indicate a skull fracture; also called periorbital ecchymosis.
- radiating pain** An area of the body from which the origin of pain or discomfort may travel.
- radiation** The transfer of heat by radiant energy—for example, heat gain from a fire.
- radioactive material** Any material that emits radiation.
- radiologic dispersal device (RDD)** Any container that is designed to disperse radioactive material; see also *dirty bomb*.
- radius** The bone on the thumb side of the forearm.
- range of motion** The full distance that a joint can be moved.
- rape** The penetration of the vagina or anus with any body part or object, or oral penetration by a sex organ, against the victim's will.
- rapid extrication technique** A technique to move a patient from a sitting position inside a vehicle

to supine on a backboard in less than 1 minute when conditions do not allow for standard immobilization.

rapid full-body scan A thorough, 60- to 90- second review of the patient's body to identify injuries that must be managed or protected immediately; conducted during the primary survey.

rapport A trusting relationship that you build with your patient.

reassessment A step within the patient assessment process that is performed at regular intervals during the assessment process to identify and treat changes in a patient's condition. A patient in unstable condition should be reassessed every 5 minutes, whereas a patient in stable condition should be reassessed every 15 minutes.

rebound tenderness Parietal pain that the patient feels when pressure is released as opposed to when pressure is applied; characteristic of appendicitis; suggestive of a serious and potentially life-threatening condition.

receptor A specialized area in tissue that initiates certain actions after specific stimulation.

reciprocity The recognition by one state of another state's licensure, allowing a health care professional from another state to practice in the new state.

recovery position A side-lying position used to maintain a clear airway in unresponsive patients who are breathing adequately and do not have suspected injuries to the spine, hips, or pelvis.

rectal Through the rectum; a medication delivery route.

rectum The lowermost end of the colon.

red blood cells (RBCs) The formed elements in the blood that contain hemoglobin and are responsible for carrying oxygen to the tissues; also called erythrocytes.

reduction Repositioning of a bone to near its normal position after a fracture or dislocation.

referred pain The pain felt in an area of the body other than the area where the cause of pain is located.

refractory Describes a disease or condition that does not respond to treatment.

rehabilitation area The area that provides protection and treatment to all personnel working at an emergency; here, workers are medically monitored and receive any needed care as they enter and leave the scene.

rehabilitation supervisor In incident command, the person who establishes an area that provides protection for responders from the elements and the situation.

renal dialysis A technique for filtering the blood of its toxic wastes, removing excess fluids, and restoring the normal balance of electrolytes.

renal pelvis A cone-shaped collecting area that connects the ureter and the kidney.

renin-angiotensin system System located in the kidney that helps to regulate fluid balance and blood pressure.

repeater A special radio station radio that receives messages and signals on one frequency and then automatically retransmits them on a second frequency.

res ipsa loquitur Theory of negligence that assumes an injury can only occur when a negligent act occurs.

rescue supervisor In incident command, the person appointed to determine the type of equipment and resources needed for a situation involving extrication or special rescue; also called the extrication supervisor.

residual volume The air that remains in the lungs after maximal expiration.

respiration The inhaling and exhaling of air; the physiologic process that exchanges carbon dioxide from fresh air; also, the exchange of gases that occurs at the pulmonary and cellular levels.

respiratory acidosis A pathologic condition characterized by a blood pH of less than 7.35 and caused by accumulation of acids in the body from a respiratory cause such as inadequate ventilation.

respiratory alkalosis A pathologic condition characterized by a blood pH of greater than 7.45 and

caused by an accumulation of bases in the body from a respiratory cause such as overaggressive ventilation.

respiratory arrest The absence of respirations with detectable cardiac activity.

respiratory distress A clinical state characterized by increased respiratory rate, effort, and/or work of breathing.

respiratory failure A clinical state of inadequate oxygenation, ventilation, or both.

respiratory rate The number of ventilatory cycles in a unit of time, usually 1 minute; also known as the ventilation rate.

respiratory syncytial virus (RSV) A virus that causes an infection of the lungs and breathing passages; can result in other serious illnesses that affect the lungs or heart, such as bronchiolitis and pneumonia; highly contagious and spread through droplets.

respiratory system All the structures of the body that contribute to the process of breathing, consisting of the upper and lower airways and their component parts.

responsiveness The way in which a patient responds to external stimuli, including verbal stimuli (sound), tactile stimuli (touch), and painful stimuli.

reticular activating system (RAS) A structure located in the upper brainstem; responsible for maintenance of consciousness, specifically a person's level of arousal.

retina The light-sensitive area of the eye where images are projected; a layer of cells at the back of the eye that changes the light image into electrical impulses, which are carried by the optic nerve to the brain.

retinal detachment Separation of the retina from its attachments at the back of the eye.

retractions Movements in which the skin pulls in around the ribs during inspiration; the drawing in of the intercostal muscles and the muscles above the clavicles that can occur in respiratory distress.

retrograde amnesia The inability to remember events leading up to a head injury.

retroperitoneal space The space between the abdominal cavity and the posterior abdominal wall, which contains the kidneys, certain large vessels, and parts of the gastrointestinal tract.

retroperitoneum The space behind the peritoneum.

return of spontaneous circulation (ROSC) The return of a pulse and effective blood flow to the body in a patient who previously was in cardiac arrest.

reverse triage A triage process in which efforts are focused on those who are in respiratory and cardiac arrest and different from conventional triage where such patients would be classified as deceased. Used in triaging multiple victims of a lightning strike.

Revised Trauma Score (RTS) A scoring system used for patients with head trauma.

rhabdomyolysis The destruction of muscle tissue leading to a release of potassium and myoglobin.

Rh factor An antigen found on the red blood cells of most people; in pregnancy, a woman's body can create antibodies against this, which can be problematic to future pregnancies.

rhonchi Coarse, low-pitched, rattling breath sounds heard in patients with chronic mucus in the upper airways.

ricin A neurotoxin derived from mash that is left from the castor bean; causes pulmonary edema and respiratory and circulatory failure leading to death.

rigor mortis Stiffening of the body muscles caused by chemical changes within muscle tissue; a definitive sign of death.

rooting reflex An infant reflex that occurs when something touches an infant's cheek; the infant instinctively turns the head toward the touch.

route of exposure The manner by which a toxic substance enters the body.

rule of nines A system that assigns percentages to sections of the body, allowing calculation of the amount of skin surface involved in the burn area.

rule of palms A system that estimates total body surface area burned by comparing the affected area with the size of the patient's palm, which is roughly equivalent to 1% of the patient's total body surface area.

rupture of membranes The rupture of the amniotic sac, which normally occurs during labor.

sacral edema Swelling that presents around the sacral region of the spinal column.

sacroiliac joints The connection points between the pelvis and the vertebral column.

sacrum One of three bones that make up the pelvic ring; consists of five fused sacral vertebrae.

saddle joint Two saddle-shaped articulating surfaces oriented at right angles to each other so that complementary surfaces articulate with each other, such as in the thumb.

safe zone An area of protection providing safety from the danger zone (hot zone).

safety data sheet (SDS) A form provided by manufacturers and compounders (blenders) of chemicals, containing information about chemical composition, physical and chemical properties, health and safety hazards, emergency response, and waste disposal of a specific material; this term has replaced material safety data sheet.

safety officer In incident command, the person who monitors the scene for conditions or operations that may present a hazard to responders and patients; the safety officer may stop an operation when responder safety is an issue.

sagittal (lateral) plane A plane of the body that passes vertically from front to back, dividing the body into left and right portions.

salicylates Aspirin-like drugs.

saline lock A type of intravenous (IV) access device that allows an active IV site to be maintained without having to run fluids through the vein, also called a buff cap or intermittent site.

salivary glands The glands that produce saliva to keep the mouth and pharynx moist.

SAMPLE history A brief history of a patient's condition to determine signs and symptoms, allergies, medications, pertinent past history, last oral intake, and events leading up to the illness or injury.

saphenous vein The longest vein in the body; it drains the leg, thigh, and dorsum of the foot.

sarin (GB) A nerve agent that is one of the G agents; a highly volatile, colorless, and odorless liquid

that turns from liquid to gas within seconds to minutes at room temperature.

scald burn A burn produced by hot liquids or steam.

scalp The thick skin covering the cranium, which usually bears hair.

scanner A radio receiver that searches or "scans" across several frequencies until the message is completed; the process is then repeated.

scaphoid abdomen Concave abdomen (sunken abdomen or an abdomen that appears empty), which is generally the result of a ruptured diaphragm; more commonly seen in infants and children, but also seen in malnourished adults.

scapula The shoulder blade.

scene size-up A step within the patient assessment process that involves a quick assessment of the scene and the surroundings to provide information about scene safety and the mechanism of injury or nature of illness before you enter and begin patient care.

schizophrenia A complex, difficult-to-identify mental disorder with typical onset occurring during early adulthood. Dysfunctional symptoms typically become more prominent over time and include delusions, hallucinations, apathy, mutism, flat affect, a lack of interest in pleasure, erratic speech, emotional responses, and motor behavior.

school age A child age 6 to 12 years.

sciatic nerve The major nerve to the lower extremity; it controls much of the muscle function in the leg and sensation in the entire leg and foot.

sclera The tough, fibrous, white portion of the eye that protects the more delicate inner structures.

sclerosis The hardening of tissue.

scoop stretcher A stretcher that is designed to be split into two or four sections that can be fitted around a patient who is lying on the ground or other relatively flat surface; also called an orthopaedic stretcher.

scope of practice Most commonly defined by state law; outlines the emergency medical care that the advanced emergency medical technician is able to provide to the patient.

SCUBA A system that delivers air to the mouth and lungs at various atmospheric pressures,

increasing with the depth of the dive; stands for self-contained underwater breathing apparatus.

sebaceous glands Glands that produce an oily substance called sebum, which discharges along the shafts of the hairs.

secondary apnea A period of gasping respirations, falling pulse rate, and falling blood pressure that occurs after primary apnea in an infant.

secondary assessment A step within the patient assessment process in which a systematic physical exam of the patient is performed. The exam may be a full-body exam or an assessment that focuses on a certain area or region of the body, often determined through the chief complaint.

secondary blast injury A penetrating or nonpenetrating injury caused by ordnance projectiles or secondary missiles.

secondary brain injury The “aftereffects” of the primary injury; includes injuries caused by abnormal processes such as cerebral edema, increased intracranial pressure, cerebral ischemia and hypoxia, and infection; onset is often delayed following the primary brain injury.

secondary bronchi Airway passages in the lungs that are formed from the division of the right and left main stem bronchi.

secondary containment An engineered method to control spilled or released product if the main containment vessel fails.

secondary device An explosive used by terrorists that is set to explode after the initial bomb; it is intended primarily to injure responders and to secure media coverage.

secondary prevention Efforts to limit the effects of an injury or illness that you cannot completely prevent.

secondary response The body’s reaction when it is exposed to an antigen for which it already has antibodies, in which it responds by killing the invading substance.

secondary spinal cord injury Injury to the spinal cord, thought to be the result of multiple factors that result in a progression of inflammatory responses from primary spinal cord injury.

secondary triage A type of patient sorting used in the treatment area that involves re-triage of patients.

secure attachment A bond between an infant and a parent or caregiver in which the infant understands that the parents or caregivers will be responsive to the infant’s needs.

sedative-hypnotic A drug used to reduce anxiety, calm agitated patients, and help produce drowsiness and sleep; a central nervous system depressant.

seizures Episodes often characterized by generalized, uncoordinated muscular activity associated with loss of consciousness; a convulsion.

selective permeability The ability of the cell membrane to selectively allow compounds into the cell based on the cell’s current needs.

selective serotonin reuptake inhibitors (SSRIs) A class of antidepressants that inhibit the reuptake of serotonin.

self-contained breathing apparatus (SCBA) Respirator with independent air supply used by firefighters to enter toxic and otherwise dangerous atmospheres.

semen Seminal fluid ejaculated from the penis and containing sperm.

semilunar valves The two valves, the aortic and pulmonic valves, that divide the heart from the aorta and pulmonary arteries.

seminal vesicles Storage sacs for sperm and seminal fluid, which empty into the urethra at the prostate.

semipermeable Property of the cell membrane that describes the ability to allow certain elements to pass through while not allowing others to do so.

sensitivity The ability of the body to recognize a foreign substance the next time it is encountered.

sensitization Development of a sensitivity to a substance that initially caused no allergic reaction.

sensorineural deafness A permanent lack of hearing caused by a lesion or damage of the inner ear.

sensory nerves The nerves that transmit sensory input, such as touch, taste, heat, cold, and pain, from the body to the central nervous system.

separation anxiety An infant behavior that peaks between 10 to 18 months. The child may exhibit clingy behavior and fear of unfamiliar places and people.

sepsis The spread of an infection from its initial site into the bloodstream.

septic shock The type of shock that occurs as a result of widespread infection, usually bacterial; untreated, the result is multiple organ dysfunction syndrome and often death.

septum A central divider, such as the nasal septum.

serotonin A vasoactive amine that increases vascular permeability to cause vasodilation.

serum sickness A condition in which antigen-antibody complexes formed in the bloodstream deposit in sites around the body, most notably in the kidney, with resultant inflammatory reactions.

severe acute respiratory syndrome (SARS) A potentially life-threatening viral infection that usually starts with flulike symptoms.

severe airway obstruction Occurs when a foreign body completely obstructs the patient's airway. Patients cannot breathe, talk, or cough.

sexual assault An attack against a person that is sexual in nature, the most of common of which is rape.

shaken baby syndrome Bleeding within the head and damage to the cervical spine as a result of intentional, forceful shaking of an infant or small child.

shallow respirations Respirations characterized by little movement of the chest wall (reduced tidal volume) or poor chest excursion.

shock A condition in which the circulatory system fails to provide sufficient circulation to enable every body part to perform its function; also called hypoperfusion.

shoulder dystocia A complication of delivery in which there is difficulty delivering the shoulders of a newborn; the shoulder cannot get past the woman's symphysis pubis.

shoulder girdle The proximal portion of the upper extremity, made up of the clavicle, the scapula, and the humerus.

shunt A passageway that allows fluid to move from one part of the body to another or to a dialysis machine.

sickle cell disease A hereditary disease that causes normal, round red blood cells to become oblong, or sickle shaped.

side effects Any effects of a medication other than the desired ones.

sign An objective finding that can be seen, heard, felt, smelled, or measured (eg, a laceration or the patient's blood pressure) when assessing a patient to establish illness or injury.

simple access Access that is easily achieved without the use of tools or force.

simple phobia A fear that is focused on one class of objects (eg, mice, spiders, dogs) or situations (eg, high places, darkness, flying).

simplex Single-frequency radio; transmissions can occur in either direction but not simultaneously in both; when one party transmits, the other can only receive, and the party that is transmitting is unable to receive.

single command system A command system in which one person is in charge, generally used with small incidents that involve only one responding agency or one jurisdiction.

sinoatrial (SA) node The normal site of the origin of electrical impulses; located high in the right atrium, it is the heart's natural pacemaker.

sinusitis An inflammation of the paranasal sinuses.

situational awareness Knowledge and understanding of one's surroundings and the ability to recognize potential risks to the safety of the patient or the emergency medical services team.

six Ps of musculoskeletal assessment Pain, Paralysis, Paresthesias, Pulselessness, Pallor, and Pressure.

size-up The ongoing process of information gathering and scene evaluation to determine appropriate strategies and tactics to manage an emergency.

skeletal muscle Muscle that is attached to bones and usually crosses at least one joint; striated, or voluntary, muscle.

skeleton The framework that gives the body its recognizable form; also designed to allow motion of the body and protection of vital organs.

- skull** The structure at the top of the axial skeleton that houses the brain and consists of the 28 bones that comprise the auditory ossicles, the cranium, and the face.
- slander** False and damaging information about a person that is communicated by the spoken word.
- sling** A bandage or material that helps to support the weight of an injured upper extremity.
- small intestine** The portion of the digestive tube between the stomach and the cecum, consisting of the duodenum, jejunum, and ileum.
- smallpox** A highly contagious disease; it is most contagious when blisters begin to form.
- small-volume nebulizer** A respiratory device that holds liquid medicine that is turned into a fine mist. The patient inhales the medication into the airways and lungs as a treatment for conditions like asthma.
- smooth muscle** Involuntary muscle; it constitutes the bulk of the gastrointestinal tract and is present in nearly every organ to regulate automatic activity.
- sniffing position** A position in which the patient is sitting upright or lying on the back with the head and chin thrust slightly forward to keep the airway open; the optimum head position for the uninjured child who requires airway management.
- sodium channel blockers** Antidysrhythmic medications that slow conduction through the heart.
- sodium/potassium (Na^+/K^+) pump** The mechanism by which the cell brings in two potassium (K^+) ions and releases three sodium (Na^+) ions.
- solid organs** Solid masses of tissue where much of the chemical work of the body takes place (eg, the liver, spleen, pancreas, and kidneys).
- solute** A particle, such as salt, that is dissolved in a solvent.
- solution** A liquid mixture that cannot be separated by filtering or allowing the mixture to stand.
- soman (GD)** A nerve agent that is one of the G agents; twice as persistent as sarin and five times as lethal; it has a fruity odor, as a result of the type of alcohol used in the agent; and is a contact and an inhalation hazard that can enter the body through skin absorption and through the respiratory tract.
- somatic nervous system** The part of the nervous system that regulates a person's voluntary activities, such as walking, talking, and writing.
- somatic pain** Localized pain, usually felt deeply, which represents irritation or injury to tissue, causing activation of peripheral nerve tracts.
- spacer** A device that collects medication as it is released from the canister of a metered-dose inhaler, allowing more medication to be delivered to the lungs and less to be lost to the environment.
- span of control** In incident command, the subordinate positions under the commander's direction to which the workload is distributed; the ideal supervisor/worker ratio is one supervisor for three to seven workers.
- Special Atomic Demolition Munitions (SADM)s** Small, suitcase-sized nuclear weapons that were designed to destroy individual targets, such as important buildings, bridges, tunnels, and large ships.
- special weapons and tactics (SWAT) team** A specialized law enforcement tactical unit.
- sphincters** Circular muscles that surround and, by contracting, constrict a duct, tube, or opening. Examples are found within the rectum, bladder, and blood vessels.
- sphygmomanometer** A device used to measure blood pressure.
- spice** An illicit drug consisting of a blend of synthetic cannabinoids; it can produce short- and long-term psychotic effects.
- spina bifida** A developmental defect in which a portion of the spinal cord or meninges may protrude outside of the vertebrae and possibly even outside of the body, usually at the lower third of the spine in the lumbar area.
- spinal cord** An extension of the brain, composed of virtually all nerves carrying messages between the brain and the rest of the body. It lies inside of and is protected by the spinal canal.
- spinal cord concussion** An incomplete injury of the spinal cord in which temporary dysfunction

lasts from 24 to 48 hours; may present in patients with simple compression fractures.

spinal cord contusion A bruise of the spinal cord characterized by edema, tissue damage, and vascular leakage, and caused by fracture, dislocation, or direct trauma.

spinal shock The temporary local neurologic condition that occurs immediately after spinal trauma; swelling and edema of the spinal cord begin immediately after injury, with severe pain and potential paralysis.

splenic sequestration crisis An acute, painful enlargement of the spleen caused by sickle cell disease.

splint A flexible or rigid appliance used to protect and maintain the position of an injured extremity.

spontaneous abortion Delivery of the fetus and placenta by natural causes before 20 weeks of gestation; also known as miscarriage.

spontaneous pneumothorax Pneumothorax that occurs when a weak area on the lung ruptures in the absence of major injury, allowing air to leak into the pleural space.

spontaneous respirations Breathing that occurs without assistance.

spotter A person who assists a driver in backing up an ambulance to compensate for blind spots at the rear of the vehicle.

sprain A joint injury involving damage to supporting ligaments (stretching or tearing) and partial or temporary dislocation of bone ends.

staging supervisor In incident command, the person who locates an area to stage equipment and personnel and tracks unit arrival and deployment from the staging area.

stair chair A lightweight folding device that is used to carry a responsive, seated patient up or down stairs.

standard of care Written, accepted levels of emergency medical care expected by reason of training and profession; written by legal or professional organizations so that patients are not exposed to unreasonable risk or harm.

standard precautions Protective measures that have traditionally been developed and recommended

by the Centers for Disease Control and Prevention for use in dealing with objects, blood, body fluids, and other potential exposure risks of communicable disease.

standing orders Written documents, signed by the EMS system's medical director, that outline specific directions, permissions, and sometimes prohibitions regarding patient care; also called protocols.

Star of Life The six-pointed star that identifies vehicles that meet federal specifications as licensed or certified ambulances.

Starling law A principle that states that if a muscle is stretched slightly before stimulation to contract, the muscle will contract harder; describes how increased venous return to the heart stretches the ventricles and allows for increased cardiac contractility.

START triage A patient sorting process that stands for Simple Triage And Rapid Treatment and uses a limited assessment of the patient's ability to walk, respiratory status, hemodynamic status, and neurologic status.

state-sponsored terrorism Terrorism that is funded and/or supported by nations that hold close ties with terrorist groups.

status asthmaticus A prolonged exacerbation of asthma that does not respond to conventional therapy.

status epilepticus A condition in which seizures recur every few minutes without a lucid interval or last more than 4 or 5 minutes.

statute of limitations The number of years after an incident during which a lawsuit can be filed.

steam burn A burn that has been caused by direct exposure to hot steam exhaust, as from a broken pipe.

steatorrhea Foamy, fatty stools associated with liver failure or gallbladder problems.

stem cell A type of cell that can develop into other types of cell in the body; this type of cell retains the ability to divide repeatedly without specializing and allows for continual growth and renewal.

stereotyped movements Repetitive movements that do not appear to serve any purpose.

- sterilization** A process, such as heating, that removes microbial contamination.
- sternocleidomastoid muscles** The muscles on either side of the neck that allow movement of the head.
- sternum** The breastbone.
- stimulants** Medications or chemicals that temporarily enhance central nervous system and sympathetic nervous system functioning and produce an excited state.
- stoma** A surgical opening in the body that connects an internal structure to the skin, such as in the neck to connect the trachea directly to the skin.
- straddle fracture** A fracture of the pelvis that results from landing on the perineal region.
- strain** Stretching or tearing of a muscle or tendon; also called a muscle pull.
- strangulation** Complete obstruction of blood circulation in a given organ as a result of compression or entrapment; an emergency situation causing death of tissue.
- stratum corneal layer** The outermost or dead layer of the skin.
- striated muscle** Muscle that is attached to bones and usually crosses at least one joint; also called skeletal or voluntary muscle.
- stridor** A harsh, high-pitched breath sound, generally heard during inspiration, that is caused by partial blockage or narrowing of the upper airway; may be audible without a stethoscope.
- stroke** A loss of brain function in certain brain cells that do not get enough oxygen during a cerebrovascular accident. Usually caused by obstruction of the blood vessels in the brain that feed oxygen to the brain cells.
- stroke volume (SV)** The volume of blood pumped forward from the left ventricle into the aorta with each ventricular contraction.
- subarachnoid hemorrhage** A hemorrhage into the subarachnoid space between the arachnoid membrane and the pia mater, where the cerebrospinal fluid circulates.
- subarachnoid space** The space located between the pia mater and the arachnoid membrane.
- subclavian artery** The proximal part of the main artery of the arm, which supplies the brain, neck, anterior chest wall, and shoulder.
- subclavian veins** The proximal part of the main veins of the arm, which unite with the internal jugular veins.
- subconjunctival hematoma** Bleeding into the anterior surface of the eye.
- subcutaneous** Into the tissue between the skin and muscle; a medication delivery route.
- subcutaneous emphysema** A characteristic crackling sensation felt on palpation of the skin, caused by the presence of air in soft tissues.
- subcutaneous tissue** Tissue, largely fat, that lies directly under the dermis and serves as an insulator of the body.
- subdural hematoma** An accumulation of blood beneath the dura mater but outside the brain.
- subjective information** Information that is told to you but that cannot be seen, such as the symptoms a patient describes.
- sublingual (SL)** Administration under the tongue; a medication delivery route.
- subluxation** A partial or incomplete dislocation of a joint.
- submersion** Survival, at least temporarily, after suffocation in water or other liquids; also called near drowning.
- sucking chest wound** An open or penetrating chest wall wound through which air passes during inspiration and expiration, creating a sucking sound.
- sucking reflex** An infant reflex in which the infant starts sucking when the lips are stroked.
- suction catheter** A hollow, cylindrical device used to remove fluids and secretions from the airway.
- sudden infant death syndrome (SIDS)** Unexpected death of an infant or young child that remains unexplained after a complete autopsy.
- suffix** The word part that comes after the word root, at the end of the term.
- sulfur mustard (H)** A vesicant also known as mustard gas; it is a brown-yellow, oily substance that is generally considered very persistent; has the

distinct smell of garlic or mustard; and, when released, is quickly absorbed into the skin and/or mucous membranes and begins an irreversible process of damaging the cells.

summation effect Increased effect that may occur when two drugs that have the same or similar action are given together.

superficial Closer to or on the surface of the skin.

superficial burns The burns affecting only the epidermis, characterized by skin that is red but not blistered or burned through; formerly called a first-degree burn.

superior Above what is indicated; closer to the head.

superior vena cava One of the two largest veins in the body; carries blood from the upper extremities, head, neck, and chest into the heart.

supination Turning the palms upward (toward the sky).

supine Lying faceup.

supine hypotensive syndrome Low blood pressure resulting from compression of the inferior vena cava by the weight of the gravid uterus when a woman is supine.

surfactant A liquid protein substance that coats the alveoli in the lungs, decreases alveolar surface tension, and keeps the alveoli expanded, allowing for easy expansion and recoil of the alveoli; a low level in a premature baby contributes to respiratory distress syndrome.

suspension A mixture of ground particles that are distributed evenly throughout a liquid but do not dissolve.

sutures Attachment points in the skull where the cranial bones join together.

swathe A bandage that passes around the chest to secure an injured arm to the chest.

sweat glands The glands that secrete sweat, located in the dermal layer of the skin.

sympathetic blocking agents Subdivision of the autonomic nervous system that governs the body's fight-or-flight reactions by inducing smooth muscle contraction or relaxation of the blood vessels and bronchioles; responsible for the body's response to shock and stress.

sympathetic eye movement The movement of both eyes in unison.

sympathetic nervous system Subdivision of the autonomic nervous system that governs the body's fight-or-flight reactions by inducing smooth muscle contraction or relaxation of the blood vessels and bronchioles; responsible for the body's response to shock and stress.

sympatholytics Drugs that block the actions of the sympathetic nervous system.

sympathomimetics Drugs that produce the same effects as the hormones of the sympathetic nervous system.

sympphysis A type of joint that has grown together forming a very stable connection.

symptom A subjective finding that the patient feels, but that can be identified only by the patient; for example, what the patient tells a provider during assessment.

synapse The gap between nerve cells across which nervous stimuli are transmitted.

syncopal episode Fainting; brief loss of consciousness caused by transiently inadequate blood flow to the brain.

syncope The temporary loss of consciousness and postural tone caused by diminished cerebral blood flow.

syndromic surveillance The monitoring, usually by local or state health departments, of patients presenting to emergency departments and alternative care facilities, the recording of EMS call volume, and the use of over-the-counter medications.

synergism The action of two substances such as drugs, in which the total effects are greater than the sum of the independent effects of the two substances.

synonyms Pairs of word roots, prefixes, or suffixes that have the same or almost the same meaning.

synovial fluid The small amount of liquid within a joint used as lubrication.

synovial membrane The lining of a joint that secretes synovial fluid into the joint space.

syphilis A sexually transmitted infection caused by the bacterium *Treponema pallidum*, which manifests in three stages—primary, secondary,

and tertiary—and is transmitted through direct contact with open sores.

systemic circulation The circulatory system in the body that is responsible for blood flow in all areas of the body, except for areas covered by the pulmonary circulation (blood flow from the right side of the heart to the lungs and back to the left side of the heart).

systemic complications Moderate to severe allergic reactions affecting the systems of the body.

systemic reaction A reaction that occurs throughout the body, possibly affecting multiple body systems.

systemic vascular resistance (SVR) The resistance that blood must overcome to be able to move within the blood vessels; related to the amount of dilation or constriction in the blood vessel.

systole The contraction, or period of contraction, of the heart, especially that of the ventricles.

systolic pressure The increased pressure in an artery with each contraction of the ventricles (systole).

tabun (GA) A nerve agent that is one of the G agents; is 36 times more persistent than sarin and approximately one-half as lethal; has a fruity smell; and is unique because the components used to manufacture the agent are easy to acquire and the agent is easy to manufacture.

tachycardia A rapid heart rate of more than 100 beats per minute.

tachypnea Rapid respiratory rate.

tactical medicine Emergency medical care provided by specially trained emergency medical responders, advanced emergency medical technicians, paramedics, nurses, and even physicians during a tactical situation.

tactical situation A hostage, robbery, or other situation in which armed conflict is threatened or shots have been fired and the threat of violence remains.

tactile stimulation Method of stimulating a newborn to breathe by flicking or slapping the soles of the feet or rubbing the lateral thorax.

tangential thinking Leaving the current topic in midconversation to talk about something else, inhibiting interpersonal communication.

technical rescue group A team of emergency responders from one or more departments in a region who are trained and on call for certain types of technical rescue.

technical rescue situation A rescue that requires special technical skills and equipment in one of many specialized rescue areas, such as technical rope rescue, cave rescue, and dive rescue.

telemetry A process in which electronic signals are converted into coded, audible signals; these signals can then be transmitted by radio or telephone to a receiver with a decoder at the hospital.

temporal lobe The portion of the brain that has an important role in hearing and memory.

temporomandibular joint (TMJ) The joint where the mandible meets with the temporal bone of the cranium just in front of each ear.

tendon A tough, ropelike cord of fibrous tissue that attaches skeletal muscle to bone.

tension lines The pattern of tautness of the skin, which is arranged over body structures and affects how well wounds heal.

tension pneumothorax An accumulation of air or gas in the pleural space that progressively collapses the lung with potentially fatal results.

tenting A sign of dehydration in which the skin slowly retracts after being pinched and pulled away slightly from the body.

tentorium A structure that separates the cerebral hemispheres from the cerebellum and brainstem.

teratogenic Poses a risk to the normal development or health of the unborn fetus.

term Between 38 and 42 weeks' gestation.

terminal drop hypothesis A theory that a person's mental function declines in the last 5 years preceding death.

termination of action The amount of time after the concentration of a medication falls below the minimum effective level until it is eliminated from the body.

termination of command The end of the incident command structure when an incident draws to a close and the command structure is no longer necessary.

tertiary blast injury An injury from whole-body displacement and subsequent traumatic impact with environmental objects.

tertiary bronchi Airway passages in the lungs that are formed from branching of the secondary bronchi.

testes The male reproductive organs that produce sperm and secrete male hormones; also called testicles.

testicular torsion Twisting of the testicle on the spermatic cord, from which it is suspended; associated with scrotal pain and swelling, and is a medical emergency.

tetanus A disease caused by the spore-forming bacterium *Clostridium tetani* that enters the body through a puncture wound contaminated with animal feces, street dust, or soil or that can enter through contaminated street drugs.

thalamus Structure of the diencephalon that is the sensory switchboard of the brain, through which almost all signals travel on their way in or out of the brain.

therapeutic communication Verbal and nonverbal communication techniques that encourage patients to express their feelings and to achieve a positive relationship.

therapeutic index The difference between the minimum effective concentration and the toxic level of a drug.

therapeutic threshold The minimum concentration of a drug necessary to cause the desired response.

thermal burn A burn that results from heat, usually fire.

thermal energy Energy transferred from sources that are hotter than the body, such as a flame, hot water, or steam.

thermogenesis The physiologic process of heat production in the body.

thermolysis The process of heat loss; methods include conduction, convection, radiation, evaporation, and respiration.

thermoregulation The balance between heat production and heat excretion.

third spacing The shifting of fluid into the tissues, creating edema.

thoracic duct One of two great lymph vessels; it empties into the superior vena cava.

thoracic spine The 12 vertebrae that lie between the cervical vertebrae and the lumbar vertebrae. One pair of ribs is attached to each of the thoracic vertebrae.

thorax The chest cavity that contains the heart, lungs, esophagus, and great vessels.

thought broadcasting The belief that thoughts are broadcast aloud and can be heard by others.

thought insertion The belief that thoughts are being thrust into one's mind by another person.

thought withdrawal The belief that thoughts are being removed from one's mind.

threatened abortion Expulsion of the fetus that is attempting to take place but has not occurred yet; usually occurs in the first trimester.

thrombin An enzyme that causes the conversion of fibrinogen to fibrin, which binds to the platelet plug, forming the final mature clot.

thrombocytopenia A reduction in the number of platelets.

thrombocytosis A condition in which the body produces too many platelets.

thromboembolism A blood clot that has formed within a blood vessel and is floating within the bloodstream.

thrombophilia A tendency toward the development of blood clots as a result of an abnormality of the system of coagulation.

thrombophlebitis Inflammation of a vein.

thrombosis A blood clot, either in the arterial or venous system.

thrombus In neurologic emergencies, the local clotting of blood in the cerebral arteries that may result in the interruption of cerebral blood flow and subsequent stroke.

thyroid cartilage A firm prominence of cartilage that forms the upper part of the larynx; the Adam's apple.

thyroid gland A large endocrine gland that is located at the base of the neck and produces and excretes hormones that influence growth, development, and metabolism.

- thyroid-stimulating hormone** Hormone that stimulates the release of thyroid hormone from the thyroid gland.
- thyroid storm** A rare, life-threatening condition that may occur in patients with thyrotoxicosis. The condition is usually triggered by a stressful event or increased volume of thyroid hormones in the circulation.
- tibia** The shin bone, the larger of the two bones of the lower leg.
- tidal volume** The amount of air (in milliliters) that is moved into or out of the lungs during one relaxed breath; approximately 500 mL for an adult.
- tissue plasminogen activator (t-PA)** A major component in the fibrinolytic system, in which clots that have already formed are lysed or disrupted, converting plasminogen to plasmin.
- toddler** A child between 1 and 3 years of age.
- tolerance** Physiologic adaptation to the effects of a drug, such that increasingly larger doses of the drug are required to achieve the same effect.
- tongue-jaw lift maneuver** A method of opening the airway for suctioning or inserting an oral airway; involves grasping the incisors or gums and lifting the jaw.
- tonic phase** In a seizure, the steady, rigid muscle contractions with no relaxation.
- tonicity** The osmotic pressure of a solution, based on the relationship between sodium and water inside and outside the cell, that takes advantage of chemical and osmotic properties to move water to areas of higher sodium concentration.
- tonsil-tip catheter** A suction catheter with a large, semirigid suction tip, recommended for suctioning the pharynx; also called Yankauer tip.
- topical medications** Lotions, creams, and ointments that are applied to the surface of the skin and affect only that area; a medication delivery route.
- topographic anatomy** Superficial landmarks of the body that serve as guides to the structures that lie beneath them.
- tort** A wrongful act that gives rise to a civil lawsuit.
- total laryngectomy** Surgical removal of the entire larynx.
- tourniquet** A bandage or device applied to an extremity to control bleeding, used when a wound continues to bleed despite the use of direct pressure; works by compressing or constricting blood flow.
- toxicity** The risk that a substance will pose a health hazard to an individual or organism.
- toxicologic emergencies** Medical emergencies caused by toxic agents such as poisons.
- toxicology** The study of toxic or poisonous substances.
- toxidrome** The syndromelike symptoms of a poisonous agent.
- toxin** A poison or harmful substance produced by bacteria, animals, or plants.
- trabeculae** Bony rods that form the lacy network in cancellous bones and are oriented to increase weight-bearing capacity of long bones.
- trachea** The windpipe; the main conduit for air passing to and from the lungs.
- tracheal tugging** Pulling of the trachea into the neck during inspiration; a sign of increased work of breathing.
- tracheostomy** Surgical creation of a hole in the trachea.
- tracheostomy tube** A tube inserted through the hole created by a tracheostomy, used to facilitate breathing.
- traction** The act of exerting a pulling force on a body.
- trade name** The brand name that a manufacturer gives a medication; capitalized.
- tragus** The small cartilaginous projection in front of the opening of the ear.
- trajectory** The path a projectile takes after it is propelled from a weapon or explosion.
- transcutaneous** Through the skin; a medication delivery route; also called transdermal.
- transient ischemic attack (TIA)** A disorder of the brain in which brain cells temporarily stop working because of insufficient oxygen, causing strokelike symptoms that resolve completely within 24 hours of onset.
- transmigration (diapedesis)** The polymorphonuclear neutrophils permeate through the vessel wall, moving into the interstitial space.

transmission The way in which an infectious disease is spread contact, airborne, by vehicles, or by vectors.

transportation area The area in a mass-casualty incident where ambulances and crews are organized to transport patients from the treatment area to receiving hospitals.

transportation supervisor In incident command, the person in charge of the transportation sector in a mass-casualty incident who assigns patients from the treatment area to awaiting ambulances in the transportation area.

transverse (axial) plane An imaginary plane passing horizontally through the body at the waist, dividing it into top and bottom halves.

trauma emergencies Emergencies that are the result of physical forces applied to the body; injuries.

trauma lethal triad A combination of hypothermia, coagulopathy (poor blood clotting), and acidosis that is a major contributor to death in patients with severe traumatic bleeding.

trauma score A score that relates to the likelihood of patient survival of traumatic injuries with the exception of a severe head injury. It calculates a number from 1 to 16, with 16 being the best possible score taking into account the Glasgow Coma Scale score, respiratory rate, respiratory expansion, systolic blood pressure, and capillary refill.

traumatic aortic disruption Dissection or rupture of the aorta.

traumatic asphyxia A pattern of injuries seen after a severe force is applied to the thorax, forcing blood from the great vessels and back into the head and neck.

traumatic brain injury (TBI) A traumatic insult to the brain capable of producing physical, intellectual, emotional, social, and vocational changes.

treatment area The location in a mass-casualty incident where patients are brought after being triaged and assigned a priority, where they are reassessed, treated, and monitored until transport to the hospital.

treatment supervisor In incident command, the person, usually a physician, who is in charge of

and directs emergency medical services providers at the treatment area in a mass-casualty incident.

triage The process of sorting patients based on the severity of injury and medical need to establish treatment and transportation priorities.

triage supervisor In incident command, the person in charge of the incident command triage sector who directs the sorting of patients into triage categories in a mass-casualty incident.

triceps The muscle in the back of the upper arm.

trichomoniasis A parasitic infection.

tricuspid valve The heart valve that separates the right atrium from the right ventricle.

tricyclic antidepressants (TCAs) A group of drugs used to treat severe depression and manage pain; even minimal dosing errors with these agents can cause toxic results.

trimesters Three segments of time, each made up of approximately 3 months, that comprise the length of a pregnancy.

tripod position An upright position in which the patient leans forward onto two arms stretched forward and thrusts the head and chin forward.

trismus The involuntary contraction of the mouth resulting in clenched teeth; occurs during seizures and head injuries.

trocár A solid boring needle.

trunked radios Computerized sharing of radio frequencies by multiple units, agencies, or systems.

trust and mistrust Refers to a stage of development from birth to approximately 18 months of age, when infants gain trust of their parents or caregivers if their world is planned, organized, and routine.

tuberculosis A chronic bacterial disease, caused by *Mycobacterium tuberculosis*, that usually affects the lungs but also can affect other organs such as the brain and kidneys; it is spread by cough and can lie dormant in a person's lungs for decades and then reactivate.

tunica adventitia The outer layer of tissue of a blood vessel wall, composed of elastic and fibrous connective tissue.

- tunica intima** The smooth, thin, inner lining of a blood vessel.
- tunica media** The middle and thickest layer of tissue of a blood vessel wall, composed of elastic tissue and smooth muscle cells that allow the vessel to expand or contract in response to changes in blood pressure and tissue demand.
- turbinates** Bony shelves that extend from the lateral walls of the nose into the nasal passageway; increase the surface area of the nasal mucosa, improving filtration, warming, and humidification of inhaled air.
- turgor** The ability of the skin to resist deformation; tested by gently pinching skin on the forehead or back of the hand.
- two- to three-word dyspnea** A severe breathing condition in which a patient can speak only two to three words at a time without pausing to take a breath.
- tympanic membrane** The eardrum; a thin, semi-transparent membrane in the middle ear that transmits sound vibrations to the internal ear by means of auditory ossicles.
- type 1 diabetes** The type of diabetic disease that usually starts in childhood and requires insulin for proper treatment and control.
- type 2 diabetes** The type of diabetic disease that usually starts later in life and often can be controlled through diet and oral medications.
- ulcerative colitis** Generalized inflammation of the inner lining of the colon that results in a weakened, dilated rectum, making it susceptible to infection and bleeding.
- ulcers** Abrasions of the stomach or small intestine.
- ulna** The inner bone of the forearm, on the side opposite the thumb.
- ultra high-frequency (UHF) band** Radio frequencies between 300 and 3,000 MHz.
- ultrasonography** The use of a special device that uses sound waves to determine the location and shape of internal tissues and organs.
- umbilical cord** The conduit connecting woman to infant via the placenta; contains two arteries and one vein.
- umbilical vein catheters (UVCs)** Special catheters designed to be inserted into the umbilical cord.
- unified command system** A command system used in larger incidents in which there is a multi-agency response or multiple jurisdictions are involved.
- unilateral** Occurring or appearing on only one side of the body.
- unintended effects** Actions that are undesirable but pose little risk to the patient.
- untoward effects** Actions that can be harmful to the patient.
- uremia** The presence of excessive amounts of urea and other waste products in the blood.
- uremic frost** A powdery buildup of uric acid, especially on the face.
- ureter** A small, hollow tube that carries urine from the kidneys to the bladder.
- urethra** The canal that conveys urine from the bladder to outside the body.
- urinary bladder** A sac behind the pubic symphysis made of smooth muscle that collects and stores urine.
- urinary retention** Incomplete emptying of the bladder or a complete lack of ability to empty the bladder.
- urinary system** The organs that control the discharge of certain waste materials filtered from the blood and excreted as urine.
- urinary tract infections (UTIs)** Infections, usually of the lower urinary tract (urethra and bladder), which occur when normal flora bacteria or other bacteria enter the urethra and grow.
- urostomy** The procedure to create an opening (stoma) between the urinary system and the surface of the skin, allowing urine to drain through a stoma in the abdominal wall instead of through the urethra.
- urticaria** Small areas of generalized itching and/or burning that appear as multiple raised areas on the skin; hives. May be one of the warning signs of impending anaphylaxis.
- uterine inversion** A potentially fatal maternal complication of childbirth in which the placenta fails to detach properly and results in the uterus turning inside out.
- uterine rupture** Rupture of the uterus, usually by trauma, that can result in life-threatening hemorrhage in the woman and fetus.

uterus The muscular organ situated between the urinary bladder and the rectum, where the fetus grows; also called the womb; responsible for contractions during labor.

V agent (VX) One of the G agents; it is a clear, oily agent that has no odor and looks like baby oil; more than 100 times more lethal than sarin and is extremely persistent.

vagina The muscular tube that forms the lower part of the female reproductive tract; connects the uterus with the vulva (the external female genitalia); also called the birth canal.

vaginal orifice Opening of the vagina.

vaginal yeast infections Infections caused by the fungus *Candida albicans*, in which fungi overpopulate the vagina.

vagus nerve The cranial nerve (X) that provides motor functions to the soft palate, pharynx, and larynx and carries taste bud fibers from the posterior tongue, sensory fibers from the inferior pharynx, larynx, thoracic, and abdominal organs, and parasympathetic fibers to thoracic and abdominal organs.

vapor hazard The danger posed by an agent that enters the body through the respiratory tract.

varicose veins Veins on the leg that are large, twisted, and ropelike and can cause pain, swelling, or itching.

vasa deferentia The spermatic duct of the testicles; also called vas deferens.

vasculitis An inflammation of the blood vessels.

vasoactive amines Substances such as histamine and serotonin that increase vascular permeability.

vasoconstriction Narrowing of the diameter of a blood vessel.

vasodilation Widening of a blood vessel.

vasodilator medications The medications that work on the smooth muscles of the arterioles and/or the veins.

vasodilatory shock A type of shock related to relaxation of the blood vessels, allowing blood to pool and impairing circulation.

vaso-occlusive crisis Ischemia and pain caused by sickle-shaped red blood cells that obstruct blood flow to a portion of the body.

vasovagal reaction A reaction consisting of precordial distress, anxiety, nausea, and sometimes syncope.

vector-borne transmission The use of an animal or insects to spread an organism from one person or place to another.

veins The blood vessels that transport unoxygenated blood back to the heart.

venous sinuses Spaces between the membranes surrounding the brain that are the primary means of venous drainage from the brain.

venous thrombosis The development of a stationary blood clot in the venous circulation.

ventilation The exchange of air between the lungs and the air of the environment, spontaneously by the patient or with assistance.

ventral The anterior surface of the body.

ventral respiratory group (VRG) A portion of the medulla oblongata that is responsible for modulating breathing during speech.

ventricle In the context of the circulatory system, one of two lower chambers of the heart; in the context of the neurologic system, hollow storage areas in the brain.

ventricular fibrillation (VF) Disorganized, ineffective twitching of the ventricles, resulting in no blood flow and a state of cardiac arrest.

ventricular tachycardia (VT) Rapid heart rhythm in which the electrical impulse begins in the ventricle (instead of the atrium), which may result in inadequate blood flow and eventually deteriorate into cardiac arrest.

venules Very small, thin-walled vessels that connect capillaries to larger veins.

vernix caseosa A white, cheesy substance that covers the fetus.

vertebrae The 33 bones that make up the spinal column.

vertebral body Anterior weight-bearing structure in the spine made of cancellous bone and surrounded by a layer of hard, compact bone that provides support and stability.

vertebral column The spine or primary support structure of the body that houses the spinal cord and the peripheral nerves.

- vertical compression** A type of injury typically resulting from a direct blow to the crown of the skull or rapid deceleration from a fall through the feet, legs, and pelvis, possibly causing a burst fracture or disk herniation.
- vertical shear** The type of pelvic fracture that occurs when a massive force displaces the pelvis superiorly.
- very high-frequency (VHF) band** Radio frequencies between 30 and 300 MHz; the VHF spectrum is further divided into high and low bands.
- vesicants** Blister agents; the primary route of exposure for this agent is through the skin.
- vesicular breath sounds** Normal breath sounds made by air moving in and out of the alveoli.
- vesicular sounds** Fine and faint normal breath sounds noted in the lateral wall of the chest from the smaller bronchioles and alveoli.
- vestibule** Small space at the beginning of an opening.
- vials** Small glass bottles for medications; may contain single or multiple doses.
- video laryngoscopy** Visualization of the vocal cords, and thereby placement of the endotracheal tube that is facilitated by use of a video camera and monitor.
- viral hemorrhagic fevers (VHFs)** A group of diseases caused by viruses that include the Ebola, Rift Valley, and yellow fever viruses, among others. This group of viruses causes the blood in the body to seep out from the tissues and blood vessels.
- virulence** A measure of the disease-causing ability of a microorganism.
- viruses** Germs that require a living host to multiply and survive.
- visceral pain** Crampy, aching pain deep within the body, the source of which is usually difficult to pinpoint; common with genitourinary problems.
- visceral pleura** The pleural membrane that covers the lungs.
- vital capacity** The amount of air that can be forcibly expelled from the lungs after breathing in as deeply as possible.
- vital signs** Clinical measurements that indicate the current state of the body and how well it is functioning.
- vitreous humor** A jellylike substance found in the posterior compartment of the eye between the lens and the retina.
- volatility** Describes how long a chemical agent will stay on a surface before it evaporates.
- volume on hand** The amount of fluid you have on hand, such as the amount of fluid in an intravenous bag or the amount of fluid in a vial of medication.
- voluntary activities** The actions that we consciously perform, in which sensory input determines the specific muscular activity.
- voluntary muscle** Muscle that is under direct voluntary control of the brain and can be contracted or relaxed at will; skeletal, or striated, muscle.
- Volutrol** A special type of microdrip set; allows you to fill a large drip chamber with a specific amount of fluid to avoid fluid overload.
- V/Q mismatch** A measurement that examines how much gas is being moved effectively and how much blood is gaining access to the alveoli.
- vulva** The female external genitalia; also called the pudendum.
- warm zone** The area located between the hot zone and the cold zone at a hazardous materials incident. The decontamination corridor is located in the warm zone.
- weapon of mass casualty (WMC)** Any agent designed to bring about mass death, casualties, and/or massive damage to property and infrastructure (bridges, tunnels, airports, and seaports); also known as a weapon of mass destruction.
- weapon of mass destruction (WMD)** Any agent designed to bring about mass death, casualties, and/or massive damage to property and infrastructure (bridges, tunnels, airports, and seaports); also known as a weapon of mass casualty.
- weaponization** The creation of a weapon from a biologic agent generally found in nature and that causes disease; the agent is cultivated, synthesized, and/or mutated to maximize the target population's exposure to the germ.

wheel A raised, swollen, well-defined area on the skin resulting from an insect bite or allergic reaction.

wheeled ambulance stretcher A specially designed stretcher that can be rolled along the ground. A collapsible undercarriage allows it to be loaded into the ambulance; also called an ambulance stretcher.

wheezing A high-pitched, whistling breath sound that is most prominent on expiration, and which suggests an obstruction or narrowing of the lower airways; occurs in asthma and bronchiolitis.

whiplash An injury to the neck in which hyperextension occurs as a result of the head moving abruptly forward or backward; can be difficult to differentiate from injuries that involve cervical bony structures and the spine.

white blood cells (WBCs) Blood cells that have a role in the body's immune defense mechanisms; they provide immunity, fight infection, and remove dead cells; also called leukocytes.

wind-chill factor A measurement that takes into account the temperature and wind velocity in calculating the effect of a given ambient temperature on living organisms.

withdrawal syndrome A predictable set of signs and symptoms, usually involving altered central nervous system activity, that occurs after the abrupt cessation of a drug or after rapidly decreasing the usual dosage of a drug.

word root The foundation of a word; establishes the basic meaning of a word.

work In the context of kinematics, the product of force times distance.

work of breathing An indicator of oxygenation and ventilation. Work of breathing reflects the child's attempt to compensate for hypoxia.

xanthines A classification of medications that affect the respiratory smooth muscle and that relax bronchiole smooth muscles, stimulate cardiac muscle, and stimulate the central nervous system.

xiphoid process The narrow, cartilaginous lower tip of the sternum.

Zika A type of virus that is transmitted by the *Aedes aegypti* mosquito in which the majority of infected persons are asymptomatic; transmission can occur from an infected mother to her fetus, and from an infected male to his sexual partners.

zone of coagulation The reddened area surrounding the leathery and sometimes charred tissue that has sustained a full-thickness burn; point of maximum damage.

zone of hyperemia In a thermal burn, the area that is least affected by the burn injury; an area of increased blood flow where the body is attempting to repair injured but otherwise viable tissue.

zone of injury The entire affected area in a bone or joint injury, which may include the surrounding soft tissues, especially to the adjacent nerves and blood vessels.

zone of stasis The peripheral area surrounding the zone of coagulation that has decreased blood flow and inflammation; it can undergo necrosis within 24 to 48 hours after the injury, particularly if perfusion is compromised because of burn shock.

zygoma The quadrangular bone of the cheek, articulating with the frontal bone, the maxillae, the zygomatic processes of the temporal bone, and the great wings of the sphenoid bone.

zygote A fertilized egg.

Index

 physical changes, 440, 440*f*
 psychosocial changes, 440
 neonates and infants, 430–434, 430*f*
 physical changes, 430–433, 431–432*f*
 psychosocial changes, 433–434, 433–434*t*
 older adults, 440–445
 physical changes, 440–445, 441–442*f*, 444*f*
 psychosocial changes, 445, 445*f*
 school-age children, 437
 physical changes, 437, 437*f*
 psychosocial changes, 437
 toddlers and preschoolers, 434–436
 physical changes, 434–435, 434–435*f*
 psychosocial changes, 436
 lifting and moving patients
 backboard or stretcher, lifting and carrying a patient on, 225–228, 225*t*
 diamond carry, 226–228, 228*f*
 one-handed carrying technique, 228
 planning the move, 226
 weight and distribution, 225–226
 bariatrics, 243
 body mechanics, 217–221
 anatomy review, 217–218, 218*f*
 proper hold, 219–221, 221*f*
 proper lifting technique, 219
 directions and commands, 221–222
 emergency moves, 228–230, 230*f*, 232*f*
 geriatrics, 241–242, 242*f*
 introduction to, 216–217
 medical restraints, 254
 nonurgent moves, 235–241
 direct ground lift, 236
 extremity lift, 237
 transfer moves, 237–241
 patient-moving equipment, 243–253
 backboards, 248–249, 249*f*, 252
 bariatric stretchers, 245, 245*f*
 basket stretchers, 250, 250*f*
 decontamination, 253
 flexible stretchers, 248, 248*f*
 loading wheeled stretcher into an ambulance, 246–248, 246*f*, 248*t*
 neonatal isolettes, 253, 253*f*
 pneumatic and electronic powered wheeled stretchers, 245, 246*f*

portable/folding stretchers, 248, 248*f*
 scoop stretchers, 250, 250*f*
 stair chairs, 250–252, 251*f*
 vacuum mattresses, 249–250
 wheeled ambulance stretcher, 243–245, 244*f*
 patient positioning, 253–254
 personnel considerations, 254–255
 safe reaching and pulling, principles of, 222–225, 222*f*
 bed, moving a patient across, 223
 patient, log rolling, 224, 224*f*
 two-person body drag, 223
 wheeled ambulance stretcher, rolling, 224–225, 224*f*
 urgent moves, 230–235
 rapid extrication technique, 231–235, 232*t*
 ligament, 274, 1538
 light burns, 1375–1376
 lightning, 1679
 limb presentation, 1690–1691, 1690*f*
 limbic system, 330, 330*f*
 linear skull fractures, 1407
 lipolysis, 1073
 lithium, 1162
 liver, 338–339
 LMA. *See* laryngeal mask airway
 load-distributing band (LDB), 827–828, 827*f*
 local cold injuries, 1605
 frostbite, 1605–1606, 1606*f*
 frostnip, 1605
 immersion foot, 1605
 local reaction, 716, 1116
 lone wolf terrorist attack, 1996
 longitudinal axis, 188
 longitudinal section, 189
 lower airway emergencies, in pediatrics, 1747–1749
 asthma, 1747–1748
 bronchiolitis, 1748–1749
 pertussis, 1749
 pneumonia, 1748
 lumbar spine, 282
 lumen, 947
 lung compliance, 598
 lungs, 296–297
 luteinizing hormone, 345
 lymph nodes, 325, 2012–2013
 lymph vessels, 325
 lymphatic system, 325–326, 326–327*f*, 2012
 lymphocytes, 322
 lymphokines, 398
 lysis, 272, 697
